Catalogue

- 15 January Africa, no further data.
- 1484 Atractaspis microlepidota purchased as juvenile in 1974; 1985 preserved Hwy 25, 2.6 mi SE Jct. Hwy 146 to Pinnacles National Monument, San Benito Co., California
- 1485 Lampropeltis getulus AOR after dark, coll. D. B. Wake 1 June 1979 ± 2.0 mi S. of FSR 1050 (\approx 1 mi E. Hutton Guard Campground) on FSR 1060, NW $\frac{1}{4}$ or SW $\frac{1}{4}$ of Sect 27, T 48N, R 11W, Siskiyou Co., California
- 1486 Lampropeltis zonata coll. unknown, 18 April 1984, gift from O. S. U.
- 9 March S. side of Box Spring Mtns., Riverside Co., California
- 1487 Leichanura trivittata active at 1259 hr, 435g
- 10 March Miramar Rd. at I 805, San Diego, San Diego Co., California
- 1488 Lampropeltis getulus under board 1435 hr
- 22 March Strawberry Canyon, Berkeley Alameda Co., California
- 1489 Crotalus viridis 13.0g, Sceloporus (prey) 11.9g before preservation
- 18 April \approx 5 mi E. Newberry Springs on National Trails Hwy, San Bernardino Co., California
- 1490 Crotalus cerastes AOR 0008hr 80g Pisgah Lava Flow, San Bernardino Co., California
- 1491 Crotalus mitchelli (stomach contents only) ^{1306 hr} 815+60mm ♂ 434g clipped 1st ventral prey = Neotoma HF
- 1492 Dipsosaurus elegans, 0.8 mi E RR, 2100 hr AOR
- 19 April Pisgah Lava Flow, San Bernardino Co., California
- 1493 Crotalus mitchelli 1.1 mi W of RR, old DOR at 1921 hr.
- 1494 Dipsosaurus elegans 1.2 mi W of RR, fresh DOR at 1932 hr.
- 21 April Pisgah Lava Flow San Bernardino Co., California
- 1495 Dipsosaurus elegans 0.7 mi S. Nat'l Trails Hwy on Pisgah Crater Rd. AOR at 1930hr
- 30 April Tesla Rd near Jct. with Mines Rd., Alameda Co., California
- 1496 Crotalus viridis DOR coll. P. Kelly

Greene, H.
1985

- 3 May Corral Hollow Rd. at Rad. Tab., San Joaquin Co., California
1497 Lampropeltis getulae AOR/DOR 2053 hr
- 20 April ≈ 6 mi. SW Piagah Crater (8.9 mi S. Natl. Trails Hwy on powerline Rd.),
San Bernardino Co., California

11 January

Pisgah lava Flow, San Bernardino Co., California

Claudia Juke and I arrived here \approx 1600 yesterday after two days of working in the Los Angeles Co. Natural History Museum. Spent today walking around, taking temperatures on the lava and adjacent areas (Claudia's data), and working on an old trail she found last fall. It is \approx 2 km W of the craters, reachable by walking on a track that runs off (to the W) of the Mining Company Road to the Craters. sunny, partly cloudy, windy and chilly at first (Claudia got a max. lava surface temperature of 26.2, shaded; rocks were warm to the touch throughout midday). Saw no reptiles, but lots of scats of Saururus and Neotoma.

22-23 February

Briones Regional Park, Contra Costa Co., California

Took my natural history class to the Alhambra Valley Rd entrance both mornings. Beautiful days, the hottest on record since 1849. Still Taricha and Hyla in the ponds but most activity is evidently over - saw many egg masses of both, but only a few nests in angiosperms. Saw 7-9 adult Clemmys marmorata basking at the uppermost lagoon in late morning both days. also golden eagles, Sceloporus occidentalis (out basking), and a last fall's hatchling Lampropeltis getula - under a rock and bearing a fresh wound (bird peck?) just anterior to the cloaca.

1-2 March

Returned w/ my natural history class to the Bear Creek Rd entrance. Weather cool, windy, overcast to

Greene, H.
1985

1-2 March
(continued)

partly cloudy. Concentrated both days on the open area on top a hill, the "old archery range. Got (on successive days) 113/166 Batrachoseps, 9/3 Ensatina, several Taricha, 2/0 Sceloporus, 1/2 Eumeces, 1/3 Gerrhonotus multicarinatus, and 0/2 Contia - all under cover.

9 March

S. Slopes of Box Spring Mtns., ~~San~~ Riverside Co., California arrived here \approx 1130 hr w/ Ben Dial (Chapman College) and Robert Fisher (student at UC Irvine), a steep slope of large granite boulders among fairly open coastal shrub. Overcast w/ occasional sun. Saw 1-2 Uta, a few Sceloporus occidentalis, and many S. orcutti active on the ground and boulders. Found one scat of Lynx rufus.

Greene, H.
1985

18 April

Pisgah lava Flow, San Bernardino Co., California

Claudia Juke, Jeff Kauffman, and I arrived here (trailers) \approx 0100 hr, having left Berkeley at 1430 yesterday. Some rain on the way down and during the night here, chilly, at times very windy. Found a skinny adult Crotalus cerastes motionless in the middle of National Trails Hwy \approx 0008 hr, 25 mi E. of Newberry Springs. Didn't expect a snake so late and cold! Overcast, cool, and windy all morning (we slept late, then packed in another load from the car, $>\frac{1}{2}$ mile away). By 1230 clouds breaking up from the west and getting warmer. I walked from then until 1345, during which there was some bright sun and occasional drizzle. At 1304 hr I found an adult Crotalus mitchelli coiled at the edge of lava and hardpan slope, S. of the trailer on the S. edge of the finger that goes W and at its base. Snake turned into a hole in the lava and rattled and coiled when I hooked it out. Saw much old Sauromalus scats and some of Neotoma, but no active lizards. Jeff and Claudia walked out to the car - they saw 2 Uta and collected scats of Canis, Tyx, and Vulpes. We clipped the snake's last vertebra, weighed (434 g), measured ($815 + 60$ mm, ♂), and palpated out a Neotoma that had been swallowed head-first. After late lunch we walked from \approx 1530 - 1800. I saw only Uta.

Greene, H.
1985

18 April
(continued)

but Claudio found Uta, a Sauromalus, and a little Gopherus (^[see below 500] carapace 90 mm, 170 g [after copious defecation and urination], 3 growth annuli, suggest born season of 1981). The tortoise was head-in to a cavity in lava, and several meters out onto the flow from hard pan. After dinner we roadhunted from 1910 - 2000 and ≈ 2100 - 2130 hr, including ≈ 5 trips over the usual 2 mi stretch and one trip to Tucklow for desert. At 2110 hr, 0.8 mi E of the RR tracks, got an AOR juvenile Arizona elegans. Saw numerous Dipodomys and a few Lepus on the road. Forgot to mention earlier that when we removed the Gopherus it elevated the posterior carapace by extending hind legs, hissed, and snapped when I poked its front legs with my finger.

19 April

Sunny and windy at dawn. Saw at Uta active at 0708 hr. Worked around trailer 'til ≈ 1000 hr, then drove out to Natt. Trails Hwy, W. a few miles, and S for ≈ 6 miles on a good dirt road used by Ken Nonis for his transect here. Warm and sunny. We saw ≥ 6 Sauromalus, including one huge ♂; 1 Urosaurus; 1 Gambelia (basking on a short charred log!); numerous small Callisaurus; lots of Uta, mostly ♀♀ gravid; and a few Cnemidophorus. We went ≈ 75-100' down a mine shaft, near a fire shed in the lava and visible from the road (Nonis' "Fisgah Hilton").

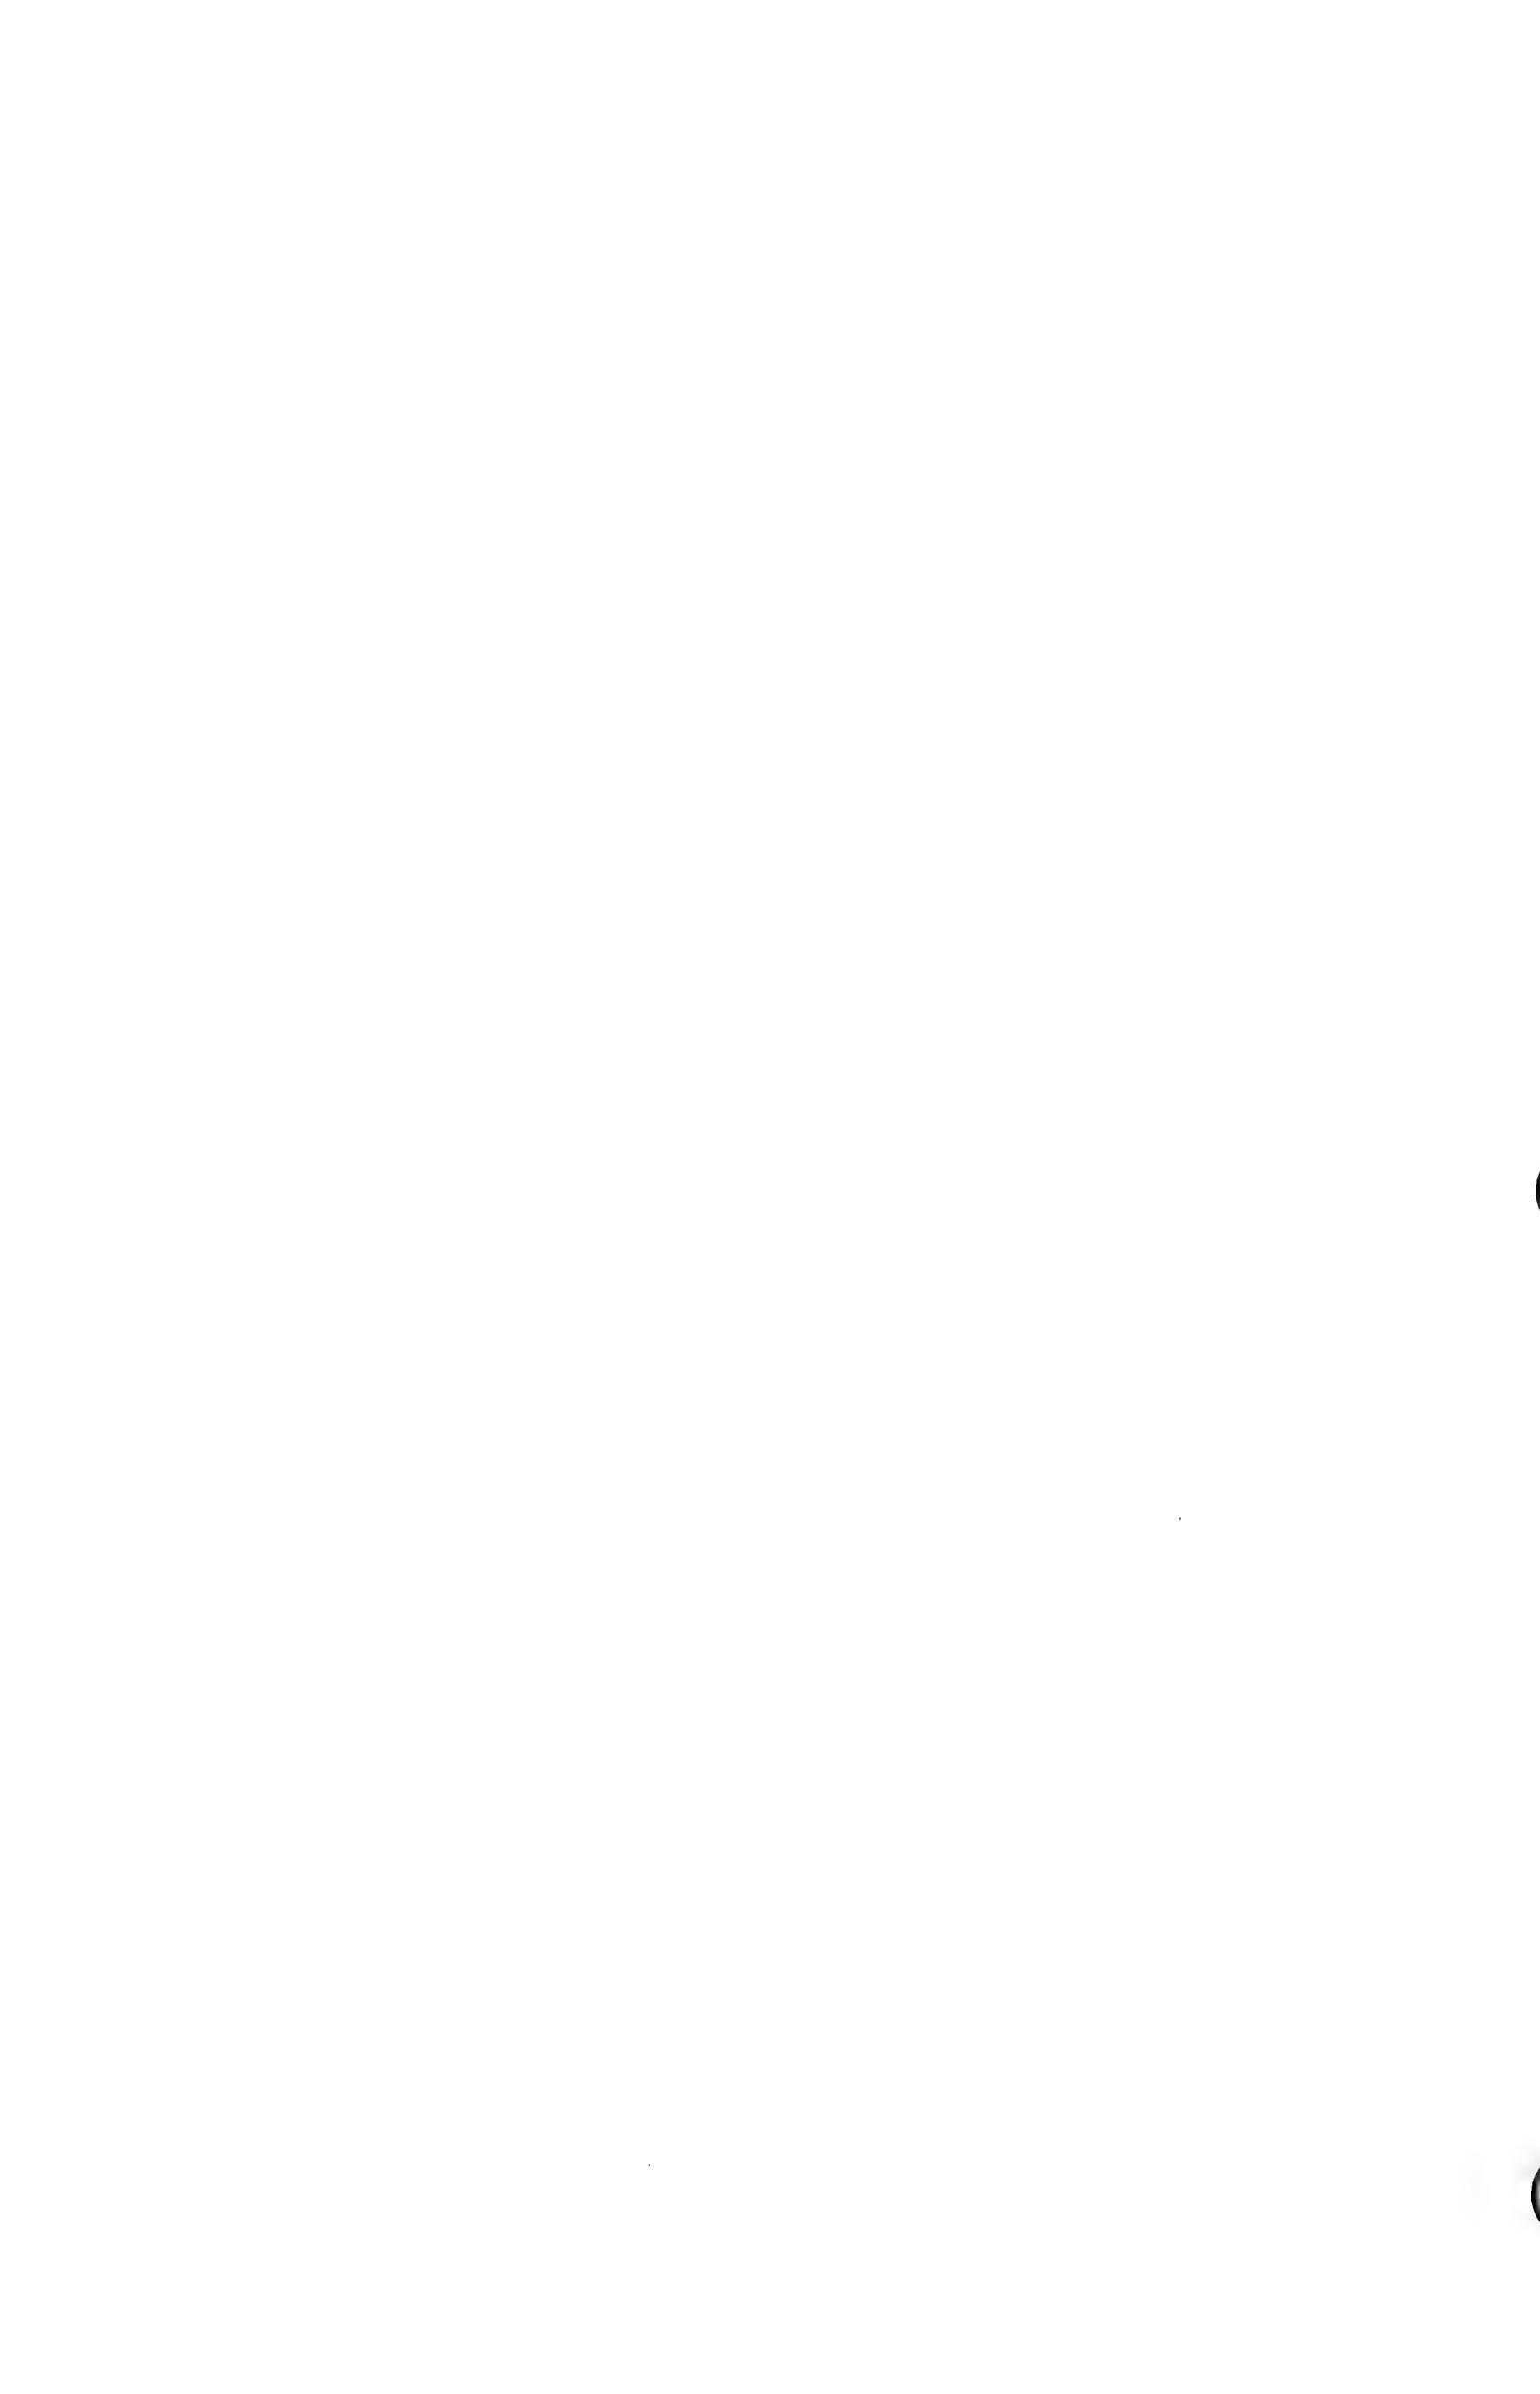

Greene, H.
1985

19 April
(continued)

but saw no animals. Saw a Buteo jamaicensis over the road in lava. Went to Barstow for supplies, and got back to the trails \approx 1715 hr. Intermittent winds all day, but nice. Road hunted \approx 1900-2115, six trips back and forth over the standard 2.1 mile stretch. Found a DOR adult Crotalus mitchelli, several hours old; a small fresh DOR C. cerastes; and a fresh DOR Arizona with a rodent in its stomach; and 2 ♂ Coleonyx. Very strong winds in the evening (shook trails hard!).

20 April High overcast and cool at dawn. Brian McCarty, Ben Dial, and Chris Austin joined us last night, and we sat around talking after breakfast til 10. Walking out, we found a small ♂ Phrynosoma platyrhinos (1030hr) active in the road and a small adult ♀ Callisaurus stationary under a creosote bush. Went to Kelso Dunes, walked for one hour, and saw no lizards. Cold and windy, overcast, all day and some rain as we drove back to Piesah \approx 1530hr. Road hunted \approx 30 miles on Natl. Trails Hwy from \approx 1915-2030 and saw no snakes, a few Dipodomys, and one large Canis latrans. Earlier in the day at the trails we saw a Falco sparverius and a possible Prairie Falcon. By 2200 hr sky clear, very cold and windy, and we are hoping for better (= hotter) weather tomorrow!

Arlene H.
1985

21 April

Sunny and windy. Released the Crotalus mitchelli (see 18 April) at capture site, took photographs, ≈ 1000 hr. It took refuge in the same crack by which originally captured. Went to Jeff's Uma study site, on N. edge of the flow — saw only Crotaphytus, Uta, an adult ♂ Callisaurus, and Chris saw one Uma. Not warm yet. Went to the Noristransact/power line road and drove to crest ridge $\approx \frac{1}{8}$ miles S. of National Trails Hwy. Saw Uta and Sceloporus near the Pisgah Hilton. Beyond lava, in creosote, found a smallish Gopherus at ≈ 1300 hr beside the road and active, w/ ≈ 10 growth annuli. St(♂) has several grooves and chips anteriorly and posteriorly on one side of the carapace, and some nicks on the plastron — coyote, lava, or what? Stopped in an area of sparse yucca and Claudia ad I each got a very large Tantilla vigilis. Jeff got a ♀ Sceloporus at the highest place we stopped. Went back to his Uma site on N. edge of the flow, but saw none. While we hunted lizards, Claudia checked out Brian McCarty's report and found large quantities of raptor pellets and droppings under the railroad bridge (i.e., over tracks) N of the crater. Returned to trail, ≈ 1630 hr and I checked the crack for the C. mitchelli — still there, several inches in, quiescent w/ head facing out. We road burled

Greene, H.

1985

21 April
(continued)

from ≈ 1835 to ≈ 2000 . Then had desert in Judlow and drove back. Only snake was a very cold adult Arizona elegans, AOR at 1930 hr, 0.7 m. S. of Nat'l Trails Hwy on Pisgah Crater Rd. Forgot to say we continued to collect scats today, including Lynx and both species of Canids. Claudia took several from a burrow mouth where we stopped for Xanthusia - a little puzzling since they were the right size for Vulpes, but the burrow struck me as more likely coyote ($\approx 8-10'' \times 12-14''$). This whole trip I've been impressed by the number of bobcat, fox, and coyote scats we've seen.

22 April

Up at 0600 to pack. Checked the Crotalus mitchelli - still in the crack, but in a side crack and $\approx 14''$ into the lava. Could see only the edge of a coil.
Left ≈ 0715 .

18 May Palm Springs, San Bernardino Co., California
arrived here last night to attend Desert Reptile
Symposium, in honor of Stebbins, at Palm
Springs Desert Museum. Near sundown we walked
around dunes on Washington avenue, a mile or
so N. of I 10. "We" includes Ben Dial, Jon
Losos, John Cawthers, Jeff Kauffmann, and
Chris Austin. Claudia saw sand spraying out
of a burrow, and we looked into see a small
Crotalus cerastes which illuded our efforts and
escaped down it.

19 May Pisgah lava Flow, San Bernardino Co., California
Claudia Juhn and I arrived here in early
afternoon and unloaded some supplies at our
trailer, \approx 1 mi W. of the crater. Driving out,
at 1513 hr, we caught a \approx 1 m Masticophis
flagellum draped over lava, beside a
Neotoma nest [specimen later accidentally released].
Went to the "Pisgah Hilton", an old mine shaft
 \approx 5 mi. E S. Natl Trails Hwy on a dirt powerline
road and \approx 2 mi W of the crater. At 1945 hr
got a 468+29 mm Crotalus mitchelli, 70g,
which was heard rattling by a student as he
walked by. Palped (empty) and released it,
after clipping second ventral. We were here to
link up w/ \approx 25 former Zoology 107 students,
and when they arrived I learned that

19 May my father died suddenly of a heart attack
(continued) last night. Claudia and I made two trips to Judlow to get the details and make travel arrangements for me to Fort Worth. Got a Crotalus cerastes and a Phyllorhynchus on the way

24 May Returned to Pisgah today, having traveled to and from Fort Worth via Ontario airport. Met Claudia at the Twin Mountain Mine office at the Crater, where we talked w/ two men about their snakebite problem. One is recovering from a cerastes bite, and they've had a recent rash of sightings. Claudia had returned here yesterday from Dawson Falls w/ Wayne Sousa and Betsy Mitchell (both UCB), who are going to watch Cnemidophorus.

Greene, H.

1985

28 July

Left Berkeley x 0845AM, Honda's odometer 15918. Stopped only for gas until I hit Newberry Springs. Right after I left the Interstate there was an old station wagon smoking beside the road - woman standing beside it nervously, man x my age and two young boys walking toward Newberry Springs. As I pulled over they ran up, told me their oil light came on. Car smoking pretty bad, so I said to stay away from it and drove the few blocks to the first bar. Caused a stir when I ran in shirtless and got their fire extinguisher. When I returned the engine was on fire, billowing black smoke, and the family was unloading the car. Yelled for them to stay away and tried to unscrew the fire extinguisher. Little kid was yelling about getting his skateboard out! Finally got the extinguisher going, started spraying under the car - got about 3 seconds of spray when it quit. At the same time there was a loud pow under the hood - everyone scattered and I jumped in a ditch beside the car. Told them once more to stay away, drove so far, found out they'd called the fire truck, and I decided to go onto to Tuolumne where I was to meet Ben Dial (Chapman College) for dinner. As I drove east out of Newberry Springs I met a fire truck going west and from several miles away could see dark smoking reaching hundreds of feet into the sky.

Greene, H.
1985

28 July
(continued)

Wondered if they were OK. We went to the Sidewinder Cafe for dinner, and before hand checked the spot - car gone, lots of black crud on highway and broken glass. Road hunted from ~~x-2045-~~ 0045 hr, mostly around Pisgah but we made one 10 mile trek down the road to Arroyo. Saw a few rabbits and a few Dipodomys. Two Kantusia vigilis AOR \approx 2100 hr. a few miles E of Newberry Spring, where Tavarish lives the road. Only snake was a Phyllorhynchus decurtatus, 1/1 mi W of RR at \approx 220 hr - ♂, \approx 30 cm TL, no food, released. Full moon, clear sky, fairly warm.

29 July

Left Ludlow \approx 900 hr, arrived at Dave Hardy's house in Tucson at \approx ~~1900~~ 1900 hr, having only stopped for gas and to stretch a couple of times. Nicest part of the drive was the first \approx 40 miles S. of Needles on U. S. 95 - some of the prettiest desert mountain scenery I've seen in California. Looked like a good road for Trimorphodon and Diadophis ^{Lichanura}.

30 July

Spent all day at the University of Arizona, examining preserved Trimorphodon and Diadophis. Had a fine talk w/ Chuck Lowe, who regaled me w/ tales of early Stebbins etc. Met George Middendorf (Howard U.), his new wife Sally, and Howard Lawler for road hunting from \approx 2100-0100, w/ an hour or so off at Howard's place in the Ariva Valley. Saw an adult Crotalus atrox between Gates Pass and the Desert Museum. Most of the time we were on the road to Silverbell and

Greene, H.
1985

- 30 July (continued) vicinity. Saw lots of Bufo alvarius and 1 Scaphiopus couchii. Saw 2 Crotalus cerastes (AOR 2245 hr, 400/00e 2359 hr), 1 C. atrox (AOR 2314 hr), and 1 Vulpes macrotis (AOR 2332 hr). also ♂3 Canis latrans, of which I saw a pair lope off among saguaros at dusk before I left the Hardy's house in Tucson (Sabino Canyon).
- 31 July Up late. Went shopping. Storms all around Tucson by late afternoon, and some rain as I left at \approx 1630 hr for Howard Lawler's place in the Arava Valley. After dinner, road hunted from \approx 2000-2400 hr. Saw 1 neonate Crotalus scutulatus, 1 Rhinocheilus lecontei, 3 Pituophis melanoleucus, 1 Hampropeltis schultzei (crawling across road in driving rain), 1 Phrynosoma solare (active on road, well after dark), several coyotes (two of which I stopped w/ mouth noises), numerous Scaphiopus couchii, and dozens of Bufo alvarius. We were driving mostly in the valley (on Sandario Rd.) or foothills (back and forth over Gates Pass Rd.). The Bufo alvarius are absurd sapos: alive they look like fresh cow pies - round, moist, and green. Dead they are large enough to be a little macabre, w/ bloody legs poking the sky. Sometimes as the car approaches they rise high and run w/ a strange fast crab walk! Got home \approx 0130 hr.

Keene, H.
1985

- 1 August Got up late. After lunch went to see Don Miles, at a place east of town on Prince Rd. Coming back, at the base of the Hardy's hill on Old Sabino Canyon Rd., I saw a woodrunner w/ an adult Crotaphytus sp. in its bill. Overcast and rather cool all day. After dinner w/ the Hardys picked up Howard Lawler and road hunted from x2130-2330 hr, from Anthony Rd to Sjo Rd on Sandario Rd, and over Gates Pass. Saw only 1 juvenile Crotalus scutulatus (zoe), 1 small adult C. atrox (HOB/SC), and 1 DOR juvenile Rhinocerurus lecontei, plus a fair number of Scaphiopus and Bufo alvarius - all on Sandario Rd. Almost full moon, so very bright when not obscured by the clouds.
- 2 August Out to Desert Museum for lunch and a visit w/ Howard Lawler (my road hunting companion all week and Curator of small animals). Rained very heavily. After dinner, Dave Hardy and I drove to Vail, ~25 miles SE of Tucson. Saw only Bufo alvarius, Scaphiopus, a Coleonyx, and one subadult Crotalus scutulatus. Not raining, large moon intermittently visible.
- 3 August After lunch drove to Cave Creek Canyon in the Chiricahua Mountains, Cochise Co. to see Barney Torberlin. Stopped for gas in Bowie, a few miles w. of the New Mexico line on I-10. Lady in store said she'd had a bad day with "drunk injuns-wish they'd go back to the reservation." Had hamburgers w/

Greene, H.
1985

3 August
(continued)

Bassey and Max Beckwith, a 16 yr-old from Marin Co. who's down here helping him. They have a live and DOR Diadophis and a Trimorphodon for me. We road hunted from \approx 2000-2300 hr, out of Portal, down Stateline Rd., and down S. on U.S. 80 to \approx 20 mi out of Douglas. Saw Scaphiopus, Bufo alvarius, 2 juv and 1 adult Crotalus atrox, 1 juv. C. scutulatus, and 4 Thamnophis marcianus. Heavy thunderstorms all around and much water on the roads, but no rain on us. Stopped at a ditch near Portal, in mesquite, to see Scaphiopus couchii and S. multiplicatus in a mixed chorus.

4 August

\approx 0900 went to a hill \approx 5 mi NE of Portal, on the dirt road to San Simon. Creosote and mesquite on the flats, ocotillo and cacti among boulders on the slopes, some rocky cliffs high on the hills. Max showed me a dead Masticophis bilineatus they had seen several days earlier, and I was impressed by the resemblance of its blue-gray skin to a dead branch. I found a Coleonyx under a pile of dead agave leaves, the only herp under \geq 25 of these I turned. At 0945 hr a cow caused a Crotalus atrox to rattle from under an ocotillo (cow started!). It was \geq 1 m long, reluctant to leave the small spot of shade it occupied, and hissed and rattled continuously.

Greene, H.
1985

4 August (continued) Our goal here was Heloderma, which have been seen in the vicinity, but we found no other herps before leaving ≈ 1000 hr. After a trip to Rodeo, New Mexico for food, Max and I went to a good site for Crotalus lepidus in Cave Creek Canyon. We hiked ≈ 1 hr from the road to Ash Spring, then ≈ 1 hr above it to an area of talus slides in forest, a few hundred feet below large cliffs on an E or SE facing slope. Trail is often in the open and rocky, winding through open forest. Lots of agaves. Just as we started walking, in thick woods, we found a juvenile Phrynosoma douglasii in the road, a close match to the leaves and rocks it sat amongst (this was at 1247hr). At 1313hr I heard rattle nearby and found a ♀ Crotalus lepidus (37g) going under rubble beside the trail. As we pulled her out Max saw ≥ 4 newborn young (open umbilical scars, opaque skin), one of which we were able to catch and photograph. At Ash Spring we drank cold, good tasting water and released a beautiful yellow Crotalus molossus (640g) Barney had sent w/us. At the uppermost rock slides Max caught 3 more C. lepidus, one of which I kept. With all these snakes I was impressed with their snappiness, constant

Greene, H.
1985

4 August
(continued)

rattling, and efforts to seek shelter rapidly. Wondered if rattling for them serves as a "pursuit invitation signal?" At 1513 hr, just as we were coming back from above to Ash Springs, through heavy woods, I heard sounds in the leaves behind me. Turned to see a \approx 80 cm Pituophis melanoleucus crawl rapidly across the trail and try to ascend an oak. After I'd seized and examined the snake, it readily ascended the tree to \approx 3 m. All along the trail, up and down, we saw lizards - several each of Sceloporus jarrovii and S. virgatus and 1 S. clarkii. After dinner went road hunting w/ George Maderday, I tramped up and down Cave Creek Canyon and two out to \approx 5 mi S. of the Portal store on the flattop to Rodeo. Saw 2 juvenile Crotalus scutulatus and 1 juvenile C. atrox, and surprisingly, an adult C. lepidus ABR at 0.6 mi S. of the Portal Store in mesquite. Snake was \approx 35 cm total length w/ an empty stomach, crawling from the east side of the road (mesquite, Cave Creek) toward the west, which is more open and has a hill with cliffs \approx 1/4 mile away. Torberlin proposes the snake was washed down out of Cave Creek Canyon in a large flash flood a few days ago.

Greene, H.

1985

5 August

Left x 0830 w/ Barrey and Max for a talus slide x 8600', near Rustlers' Point. It is a S or SE facing, steep slope, w/ oaks, pines, manzanita, and large open fields of talus. As we came over the crest to descend, heard a big commotion and saw a \approx 400 pound red bull hanging by its neck from an oak tree crotch - it had apparently lost its footing and slid into that predicament. Barrey dashed off to the car to get a saw at a Forest Service station up the road, but the bull evidently died about that time as it never moved again and I could detect no movements. Max and I began to search the talus, and w/in minutes (0940 hr) we heard then caught a large adult Crotalus pricei. It had an empty stomach and seemed light so while taking photos we offered it a Sceloporus virgatus which it ate! also saw numerous S. jarrovi. It was bright and sunny when we arrived, but dark clouds blew in from the NW and a light rain fell sporadically as we left. Next stopped downhill (still well above the Southwestern Research Station) and worked up and down road along East Turkey Creek for an hour or so. Saw lots of Sceloporus, but the only snake was a nice young adult C. molossus Barrey found sunning in front of a rock, a

Greene, H.

1985

5 August
(continued)

few meters above the creek in open woods. Hooked it out gently, which elicited only mild rattling, and into a sack - might be digesting a meal. Diving back, just down canyon from the SWRS, a large Masticophis bilineatus crossed the road and disappeared near the creek among trees - very fast. Met Vince Roth, Director of the Southwestern Research Station, who gave me a beautiful Elgaria kingii he caught today near the station. After dark made three circuits up Cave Creek Canyon to the S.W. R.S. and three trips 3.0 miles S. of Portal, from 20-2230 hrs. Saw 2 Crotalus scutulatus juveniles on the southern runs (2052 hr, 2154 hr, not collected). Got a large, beautiful Elaphe triaspis just crawling onto the road in Cave Creek Canyon at 2018, 0.5 mi toward S.W.R.S. past the turn to South Fork. It lay motionless until picked up, then formed an acute S-wit and struck wildly until bagged. At 2110 hr found a large Hypsiglena torquata just hit near S.W.R.S. At 2045 hr there was a Microlophus eurylophus AOP in mesquite 1.5 mi S. of Portal, easily recognizable from w/in the car. When I restrained the snake it began wild contortions, tail display, snapping and biting, and sharp cloacal popping that was easily audible. When I examined the snake two hours later it had regurgitated a

Greene, H.
1985

5 August
(continued)

freshly ingested Leptophyllops (4g). Barney and Max had gone to New Mexico, where they collected a Gyrodion canum and a Crotalus that appears scale-wise and in coloration to be a hybrid Crotalus molossus x scutulatus. They also gave me a DOR adult C. scutulatus from New Mexico and a just hit C. molossus from Cave Creek Canyon. What a day! [Need to add some mammal notes.

Yesterday I saw an Apache Fox Squirrel on the road to Ash Spring and Ursus americanus scat on the trail above there. Have seen numerous deer, rabbits, and ground squirrels. Just dust, at 1759 hr, I encountered 4 javelina just down the paved road to Portal from Dave Hardy's house. I must stress how impossible it was to tell head from tail on the Micruroides during its display.

6 August Drove up to the collection site of Elaphe siaspis for photographs - heavily wooded on the SW, w/canyon walls nearby, open field w/oaks, then stream and canyon walls on the NE. Back to Barney's for breakfast and photographs of the snakes. The Micruroides repeated its performance, and I noticed that when the body extends and freezes, the head is tucked back acutely, enhancing resemblance to the tail. As I drove S. of Portal \approx 0930 hr, found a \approx 5' Pituophis melanoleucus stretched out on the pavement.

Reese, H.
1985

- 7 August Spent last night with Chuck and Mickey Bogert in Santa Fe, and made it to "North Pines," a cabin owned by Rob Colwells' folks in Drake, Colorado.
- 8 August To Boulder for Rob's wedding.
- 9 August Drove to Salt Lake City via Laramie and Rock Springs, Wyoming.
- 10 August Spent today w/ Ian Radinsky, Leah Radinsky (daughter), and Sharon Emerson at their house near Park City. Checked my snakes, and discovered a large scat w/ the Crotalus molossus - confirming my suspicion that it was digesting a meal when found.
- 11 August Salt Lake City to Flagstaff via I-? and Utah 89, the latter through spectacular vermilion cliffs of the canyon country. Noted that the habitat ^{northern} ~~with~~ of the Sunset Crater/San Francisco Peaks area, where Lanthanas ~~has~~ triangulum has been taken, is juniper-sage-grassland. Spent the night in the El Pueblo Motel, a cheap dump.
- 12 August Drove to Tucson, via Phoenix where I picked up a Heloderma suspectum from the Arizona Game and Fish Dept. arrived Tucson \approx 1300 hr. As I left the Hardy's house at 1808 hr, a 12 cm carapace length Gopherus agassizii was crossing their drive-way. Road hunted from \approx 1930 - 2330 hr, picking up and

Hesse, H.
1985

12 August
(continued)

dropping off Howard Hawler at his home in the Avra Valley in the course of things. No rain, dark moon, warm, as before, our route was up and down (N-S) on Sandario Rd., an area of lowland desert that is particularly moist at its' south end (it ends at the Ajo Rd.), alternated with trips over the Tucson Mountains via Mile Wide, Kinney, and Gates Pass Roads, turning west again at Camino de Oeste on the western outskirts of Tucson. Found 17 snakes and saw 2 carnivores: a fresh DOR Trimorphodon biscutatus low on the E. slopes of the Tucson Mountains (2111 hr); 2 AOR juvenile Rhinocerelus lecontei, clarkii-phase (2032 hr, not collected, in Saguaro National Monument), 2139 hr); 2 DOR Pituophis melanoleucus (1929 hr, 2354 hr); 1 AOR yearling Crotalus tigris (2136 hr); and 1 AOR juvenile C. atrox (2132 hr) on the western slopes of the Tucson Mountains. All of the above snakes came from rocky, upland desert habitats w/ lots of Saguaros. On Sandario Rd., lowland desert, we saw (didn't collect) 4 juvenile C. atrox (2146, 2149, 2151, \approx 2310 hrs.), 2 adult C. atrox (2222, \approx 2340 hr), 3 juvenile C. scutulatus (2200, 2205, 2212 hrs.), and 1 adult C. scutulatus (2227 hr). Also saw 1 Canis latrans and 1 Lynx rufus on western slopes of the Tucson Mountains.

13 August

Road hunted by myself from \approx 1930 - 2200 hr in the upland desert area described above. No rain, dark moon,

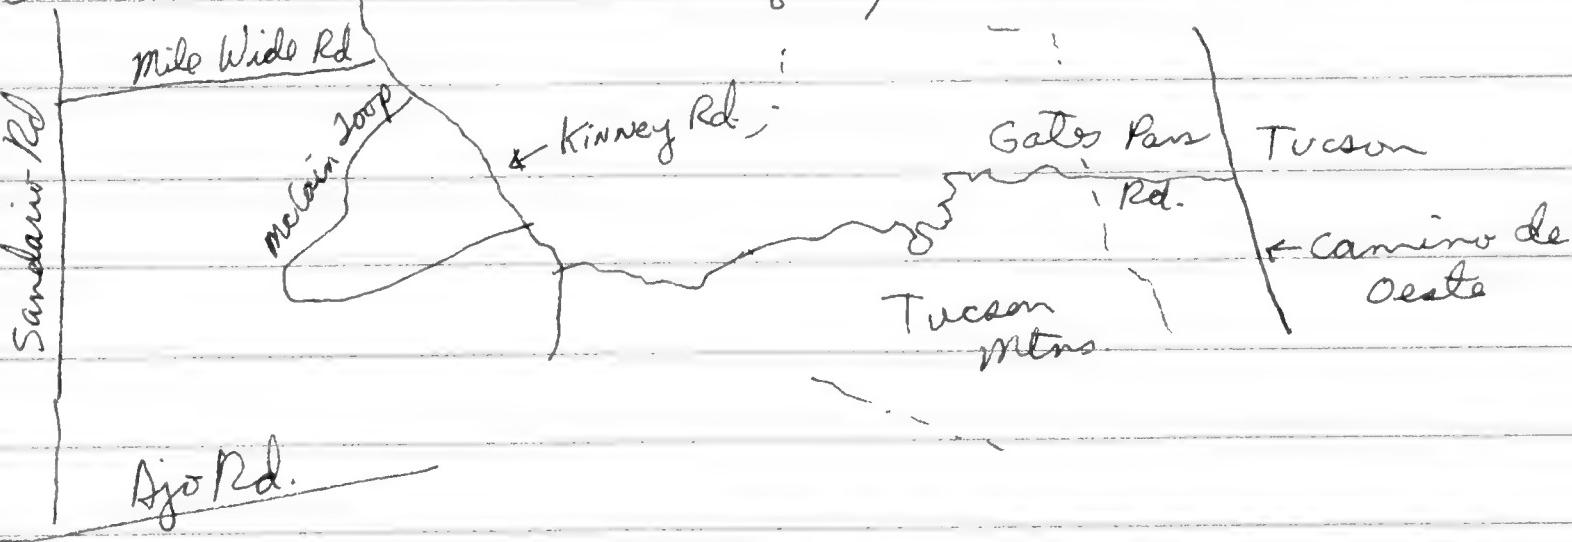

Greene, H.

1985

13 August
(continued)

hot and sunny all day. Saw only two snakes, a fresh DOR Pituophis melanoleucus at 2007 hr on Mile Wide Rd and an AOR juvenile Crotalus atrox at 2018 hr on the McCain Loop Rd (off Kinney Rd.). Also saw 5 Canis latrans and a small adult Taxidea taxus, the latter a few minutes after the little C. atrox. Big coyote chorus around midnight at the Hardy's.

14 August Hot and sunny all day, dark moon. Road hunted same route as last night, \approx 1930 - 2145 hr.

Saw only two snakes, a large ♀ AOR Trimorphodon biscutatus at 2018 hr on Mile Wide Rd. and a juvenile AOR Crotalus atrox on McCain Loop a few minutes later. The lyre snake was in rocky upland desert, lots of saguaros; I picked it up gently and it only vibrated its tail.

15 August

Drove from Tucson to Mojave, California. \approx 111°F in the shade in Needles in mid-afternoon.

16 August

Back in Berkeley \approx 1400 hr, \approx 5450 miles later.

Greene, H.
1986

25 April

Pisgah lava Flow, San Bernardino Co., California

Arrived here \approx 0130 hr w/ Zoology 165 (Herpetology) class from Berkeley; 27 students, 2 TA's, and 2 guests.

Spent the morning looking around the "Pisgah Hilton" and saw Savannahus, Cnemidophorus, Uta, Gambelia, Crotaphytus (1 ♀. w/ red, ran bipedally), ~~and~~ Callisaurus, and Dipsosaurus. Yesterday just after dusk ~~or~~ Claudia & I found 2 Arizona on the road. After lunch drove eastward.

Donner Camp, N. side of Granite Mts, San Bernardino Co.

Arrived here \approx 1430 hr and spent the afternoon exploring in the rocks. Claudia got a DOR Crotalus cerastes on Kelbaker Rd on the way in. After dinner, took one car and drove to Kelso and back, got only 1 chionactis.

26 April

at \approx 0730 hr Kathy Devaney found a juvenile Salvadora reticulata crawling among cholla and shrubs a few yards from the ranch house (umbilical scar obvious, SV \approx 725, tail \approx 80+, 330 g). Spent the morning exploring boulder slopes and the bajada sweeping NE from the ranch. I saw Cnemidophorus, Uta, and 2 Neotoma. Doug Brown found a beautiful, apparently gravid Lichanura out on the ground among boulders at \approx 0830-0900 (SV \approx 725, tail \approx 80+, 330 g). At \approx 1115 hr I found an adult Crotalus mitchelli crawling under a large boulder - rattled when I hooked

Greene, H.
1986

26 April
(continued)

it out (♀, possibly gravid, 785+67 mm, 440g, nothing palpable in stomach). At lunch others come back w/ a huge Sauronotus and an adult ♀ Salvadora hexalepis. John Carothers brought in a Crotalus mitchelli found resting under a boulder (♂?, 1000+72 mm, 991g after meal palpated), from which I palpated a Sylvilagus that had been swallowed head-first. He also caught in a cholla a large Masticophis flagellum (1205+400 mm, 474g after meal palpated) from which I palpated a Dipodomys that had been swallowed head-first. Matt Colbert found a Hypsilema torquata under a yucca log.

Breene, H.
1986

2 July

Pisgah Lava Flow, San Bernardino Co., California

arrived here \approx 2100 hr, having left Berkeley \approx noon.

Road hunted for \approx 30 min and saw 2 Phyllorhynchus and 1 Crotalus cerastes; palpated a Dipsosaurus out of the lattice and picked the snake and prey. Met Claudia Lehe and Alexis Schuler, who arrived here several days earlier. They saw an Arizona elegans on the road.

3 July

couldn't sleep because of the heat and flies, so I got up \approx 0230 and went to Ludlow for ice, juice, etc.

Saw a Phyllorhynchus near the RR tracks at 0323 hr.

Woke up \approx 0600, ate some melon, and checked out the mine shaft entrance of Pisgah Hilton for a Crotalus mitchelli. Alexis has seen several times. The snake started rattling when I poked in rocks where she indicated, but it is deep in a crevice and I couldn't see it. Had breakfast in Ludlow & then to Granite.

Donner Camp, Granite Mts., San Bernardino Co., California

arrived here to write and relax in solitude for two days. Hot, but not as bad as at Pisgah - only \approx 95°F in shade here. Went to Baker for dinner, then road hunted back and forth on Kelbaker. At sundown I walked up a rocky slope 2.5 mi N. of Kelso, where a large mountain range sprawls down to the road from the W. Soon heard a rattling at \pm my feet, and caught a famished looking little Crotalus mitchelli that was active in the rocks. It struck readily at my flashlight.

Greene, H.
1986

3 July
(continued)

Didn't have a sack, so took out the batteries and carried it in the flashlight. After dark got an adult Crotalus cerastes and a Colobosaurus just N. of where the large Kelbaker Lava Flow intersects the road, then an Avgon and a yearling (?) C. scutulatus on the way back to Kelso.

4 July Spent the day revising a chapter on defense in reptiles. Took periodic breaks to photograph rabbits and observe Anomysornophiles foraging in a 2m high Larrea. Is this secondary arboreality? These aren't any more ground squirrels than Sciurus - their "trees" are just shorter! After dinner drove to Baker for ice and juice, and got 2 Colobosaurus (again near where the lava flow crosses road, x21 mi N. Kelso), 1 Pituophis, and 1 Avgon, all AOR. Arrived at Danner Camp x2215, to find Claudia and Alexia had arrived a couple of hours earlier.

Greene, H.
1986

27 July Left Berkeley x noon and arrived in Mt. Shasta
in time for supper, after getting a room at the
Evergreen Lodge. Then drove to Grasshopper Flat,
24.1 miles N. of Bartle (Hwy 89) on Harris Spring Rd.
Arrived well before sunset, so looked for more
Phrynosoma douglasii (see R.C. Stebbins notes
for earlier this month). Saw only deer, and
it seems too cool for lizard activity. Drove
3.2 miles further north to Pumice Stone Well, a
very picturesque pond in a meadow at
x 6100' and just below Pumice Stone Mountain.
Walked around looking for Thamnophis, and
saw lots of tadpoles and recently transformed
Hyla regilla. Flipped many cow pies, and
collected 13 Ambystoma macrodactylum under
them (saw others). Road hunted from x 2030-2330
m, and saw only one Bufo boreas, one Charina
bottae, an adult and a young Erythrolion
together, and lots of rodents (Dipodomys,
Perognathus for sure).

Costa Rica
Calif: Contra Costa Co.
Arizona: Pima, Cochise Cos.
Costa Rica

Greene, H.
1987

15 June

Estación Biología La Selva, Provincia Heredia, Costa Rica

Arrived here \approx 1030hr, after a \approx 2 hour ride from the OTS office. Much has changed! Road is good all the way to Puerto Viejo, there are soldiers w/ M-16 that check all vehicles entering the town, and there is a new OTS facility on the north side of River from the station.

Left Berkeley early on the 13th, spent the night in Miami to visit Mo Donnelly and Jay and Becky Savage, and got to San Jose \approx 1500hr. Ran in to Eddie Igquierdo in Miami (he is a friend of Dixie Pierson from Berkeley and I met him at La Selva), on his way to visit Maria Teresa Koberg ("Tete") - a woman who works on sea turtle conservation in Limon. They were waiting when I emerged from customs, offered a ride, and took me on a spectacular side trip on a beautiful new highway to Grapiles. Road goes up over the crest in Braulio Carrillo national park, which was hung w/ thick white clouds and mist. Very steep terrain!

Joanne Sharpe (grad student from U. Georgia, studying ferns, cousin of Dick Sage) took me to see a hachis muta that she has watched sit in one spot for 4 weeks (more details later). When we arrived \approx 1600hr, snake was "gone," leaving a pallet of bare soil where it had lain. I began walking in

Greene, H.
1987

15 June
(continued)

a rough spiral beginning at the pallet, while Joanne stayed put bemoaning the snake's exit. Within 5 minutes she found the snake, almost hidden under ferns a few cms high! It is 1.2 m N. of the pallet, in a tight sleeping coil. Judging from the size of the coil (≈ 25 cm) and it's color (tan, not red of juveniles) I guess it to be ≈ 1.3 m. Next we entered Plot 1 (nearly) w/ Diana Hiebermann to look for a large boa she saw last week, and were soon thoroughly lost. Eventually emerged on the Sendero Occidental (we had entered on the Sendero Experimental Sur) 30-45 min later. No snakes. It rained very hard from ≈ 1830 - 2030 hr, after which I walked the new Sendero Contarana, a boardwalk through a swamp in the Ecological Reserve. Moderate number of Hyla crucifer and other frogs calling.

16 June Relocated Lachesis muta in same place as yesterday. The site is a few tens of meters from a plastic echo at ≈ 530 SES, on a heading of $\approx 210^\circ$ (≈ 5). Snake is coiled in same place, w/ head down and facing 180° (s). Ticked once when I disturbed a twig nearby. This was at 0808 hr. Next walked to station, through the Ecol. Res. swamps, out SOC and

Greene, H.
1987

16 June around the Camino Circular.
(continued) Saw a fresh
foam nest (Leptodactylus pentadactylus?) in
the swamp, a few frogs calling, and a
fresh pile of plucked feathers at the E. end
of the boardwalk w/ no associated fresho.
Two types - small w/ white base & red-brown or
~~orangeish~~ outer part, and small bicolor,
orange-brown, white, ad gray at base; ad
white base w/ black outer half, marked by
two white spots. Perhaps prey of a hawk?
Very hot and humid day - at least to me!

Thinking about Lachesis as I walked today:
maybe they mostly die from parasites, at
least the big ones? What is the effect of prey
specialization on parasitism? Someone brought
in a small Micruro nigriceps at lunch
(222+28 mm, 2.7g, no food); it thrashed,
bit readily, and prolapsed the cloaca when seized,
but coiled the tail only w/ repeated on the head
and body. Bob Margolis (U. Illinois) brought
in a Bothrops nasutus from 1400 LOC,
found this morning (282+29 mm, 17.3g, gravid
- several small ova, no food). Collin Orians (Penn.
State U.) took me to \approx 650 CES, where this AM
he found a B. nasutus, which we located
 \approx 1330 (320+28, 20.5g, no food, possibly
enlarged ova). The little viper was in a

Greene, H.
1987

16 June
(continued)

tight coil at the end of a rotten fallen limb ≈ 10 cm in diameter, facing the ~~end~~ length of the limb - ≈ 1 m, ending at a large fallen log. Snake jerked to alertness when touched w/ a snake stick, suggesting to me that it was asleep. Viper was in a great position to strike an oncoming rodent, which perhaps it would only do at night.

While walking out to see that snake, at 1302 hr,

I spied a Leptophis ^(735 + 465, 54g) nebulosus going into a crack/hole/litter at the base of a buttressed tree beside the trail at ≈ 100 CES. Snake proapsed the cloaca & thrashed when grasped, emitting a foul and distinctive smell (vaguely like agkistrodon). As soon as in the open it gaped widely, orienting to my moving hand, and struck and bit at close objects. At 1400 hr,

I was sent to the bathroom below cabina #3 where there was a Leptodeira septentrionalis on a baseboard, in the dark behind the door

(480 + 126, ♂, 16.0g, no food). This morning was sunny, hot, humid, but by 1500 hr it is dark and there is loud, long thunder. Rained until after dinner. Went w/ Joanne Sharpe to see the young Lachesis, which at 2010 hr was in the raised alert posture, facing E, and on the "original" pallet at the tree base. Thus, sometime since this morning she had

Greene, H.
1987

- 16 June moved from under the Danaea fern. Saw
(continued) several hydids on wet leaves along the trail.
- 17 June Left at \approx 0700 w/ Diana Liebesmann, Victor Robles,
Libby Knight and her brother David (she is a Berkeley
undergrad in the EAP), and Mark? (ABC reporter
from San Diego soon to travel w/ the contras and
Sandanistas in Nicaragua. We walked to Plot III,
 \approx a 45 min walk on the 550, where deep w/in
the plot they saw a matauey and a Terciopelo
yesterday. It is steep terrain. The Bothrops
asper was \approx 1 m and under the edge of a small
chunk of log in a dense, rank treefall on a
steep slope. The snake wasn't there today. The
Hachisus muta was largely concealed under a
dry fallen Welfia frond, \approx 2 m from an old
fallen tree and \leq 7 m (about equidistant)
from two adult Welfia. It was asleep, but
when I lifted the frond it pulled in its
coils and formed a tight, elevated striking coil.
The first reaction to me lifting it in the air
was slow crawling, but after I failed to
get it in the trash can on the first try it
slid to the ground and assumed an open
striking coil. Neck & anterior was
flattened in a vertical plane and the whole
body seemed inflated. It took 2-3 long
strikes at me, impressively long!

Greene, H.
1987

17 June Took \approx 10 minutes to finally get it in the can,
(continued) and I never saw it fail vibrate. No other
snakes in >2 hours of walking. Overcast.
Joanne Shaepp check the Hachisus muta at
CES 530, and it was back under the Danaca
fern w/ head facing \approx N (opposite ~~the~~ direction
from the site it was hunting last night).
It rained hard for ≥ 2 hours this afternoon.
I checked the snake at 2005 hr and it was
back at the open site, 1 m from the fern
bed, at the base of the small tree and facing
E. Very alert. Walked through the new
swamp; saw and heard Hyla loguax.
at \approx 2200 saw a nice big Smilisca
bandini on the bridge railing on the
dining hall side, where vegetation comes
up to the boardwalk.

On June 12th Rebecca Butterfield saw a
large multispecies frog chorus in the new
swamp (~~Cerro~~ Sendero Cantarana), including
hybrids, Agalychnis callidryas, and a
couple of Leptodactylus pentadactylus. She
described 2 slender yellowish snakes w/ blunt
heads and big eyes and were surely
Dipsosaurus inornatus; both were on
branches overhanging the boardwalk, and
one was sagging w/ a large food mass.

Free, H.
1987

18 June

after breakfast, measured the big *hachis* *water*:

1780 mm SV, tail 175 mm, 3.75 kg.

She seemed moderately aggressive, repeatedly forming a striking coil and keeping the body inflated and vertically flattened. She (?) seems exceptionally heavy, but the people helping me hold her couldn't palp eggs or food w/ any certainty. Before breakfast the workmen found a *Leptodeira septentrionalis* under a tire at their shed, on the edge of second growth (523+49 mm, 27.3 g).

It assumed an exaggerated S-coil, expanded the head posteriorly, and made slow awkward strikes. Tried to bite when seized. It had recently eaten a hylid w/green bones, SV 38 mm, max head width 10.5 mm, 2 g.

After lunch, went out 50' and into Plot I to photograph a large spider, feeding on what had been a yellow hylid (?) in its web. Diana Liebermann had found them this AM, when the frog was largely intact. Left at 1600 hr to check the *hachis* on CES. at 1616 hr, 250 CES, caught a *Leptophis ahaetulla* (♀ possibly gravid, 840+530 mm, 105g) crossing the trail on a grade. Snake immediately prolapsed the cloaca, emitting a strong odor very similar to the *b. nebulosus* earlier this week. Thrashed laterally and along its long axis, gaped

Greene, H.
1987

18 June and repeatedly swung round to title. At 1622 hrs
(continued) found the L. muta asleep in ferns, head facing
W. Very still and humid, no rain yet today.
Lots of snakes lately: Rodolfo (Cathy Pringle's
assistant) brought me 3 young Bothrops asper
(not neonates) yesterday (no food) and Orlando
saw another today. Joanne saw an adult
Pseudalsophis occidentalis in tangle behind the
banjo of the Old Station, which inflated its
throat, and a Chironius grandisquamans sat
on a trail. Danilo Brenes saw a young
Felis pardalis cross the Sendero Jaguar this
afternoon and tracks, probably of the same species.
He saw tracks of Felis onca on the same trail
8 days ago. After dinner walked out to check
the hachis but couldn't find the site in the
dark. Cursing back along the trail I found
a nice male Hyla septentrionalis on a leaf a few
cm above the ground. Hot, humid day, no rain.

19 June a hot, sunny morning. As early as \approx 0620 there
was a large ♂ Iguana iguana (this is one E. side of bridge)
small Cecropia, sunning w/ dewlap out.
Seemingly in prime and freshly shed, w/a
small patch of skin hanging on one foreleg.
Gave one bout of bobs as I watched. It was
perpendicular to the rising sun. When I
returned to shoot pictures at \approx 0815, saw

Greene, H.
1987

19 June (continued) a ♀ adult I ignora a few tens of m away at ≈ height, on the limb of a large tree in shade. Numerous Rhinoclemys basking on dead logs in the Rio Puerto Viejo, and an adult Caiman crocodilus on a fallen live tree that extends on the bank to river's edge. It had its mouth wide open. Joel gave me another baby Micromys nigricaudus, caught near the workman's shed in the new complex. Beth Braker walked to the South Boundary this morning; she brought back a Felis scat and saw a Mastigodryas melanurus eat an Anreiva festiva. Met Renaldo Aguilar, a guard or ranger for the Zona Protectora, who told me of finding tracks and a kill of a sloth by Panthera onca. Took him to see the Lachesis muta at CES 530, and found it asleep under the Danaea and facing SSE at ≈ 1400 hr. Sunny almost all day, but dark clouds and distant thunder at 1740 hr.

20 June Rained during the night, morning hot and humid. I am lazy and grouchy! ≈ 1000 hr checked the Lachesis muta at CES 530 - under Danaea, head pointing W. At 1040 hr Gerardo Vega directed me to a large Pseudeustes poecilonotus stretched out in grass near a Heliconia patch in the station clearing, near Cabina #1 (it was

Greene, H.
1987

20 June
(continued)

thus w/in a few meters of the origins of SOR & CES, where I have caught Pseudals in previous years.

Snake has one healthy tick and a large puncture-wound like scar on its neck, no food, 1890 mm SV, 555 mm tail, ♂, 887g. When seized immediately swimming round (it had tried to crawl away) w/ jaws agape, body inflated, bit my jeans and hung on. Repeated handling resulted in emission of a "musk" somewhat reminiscent of Echis obsoleta (which Pseudals reminds me of in various ways). After dinner ~10 of us went to a dance in Chilamate, a few km west of Puerto Viejo. It was held in a school, as a benefit.

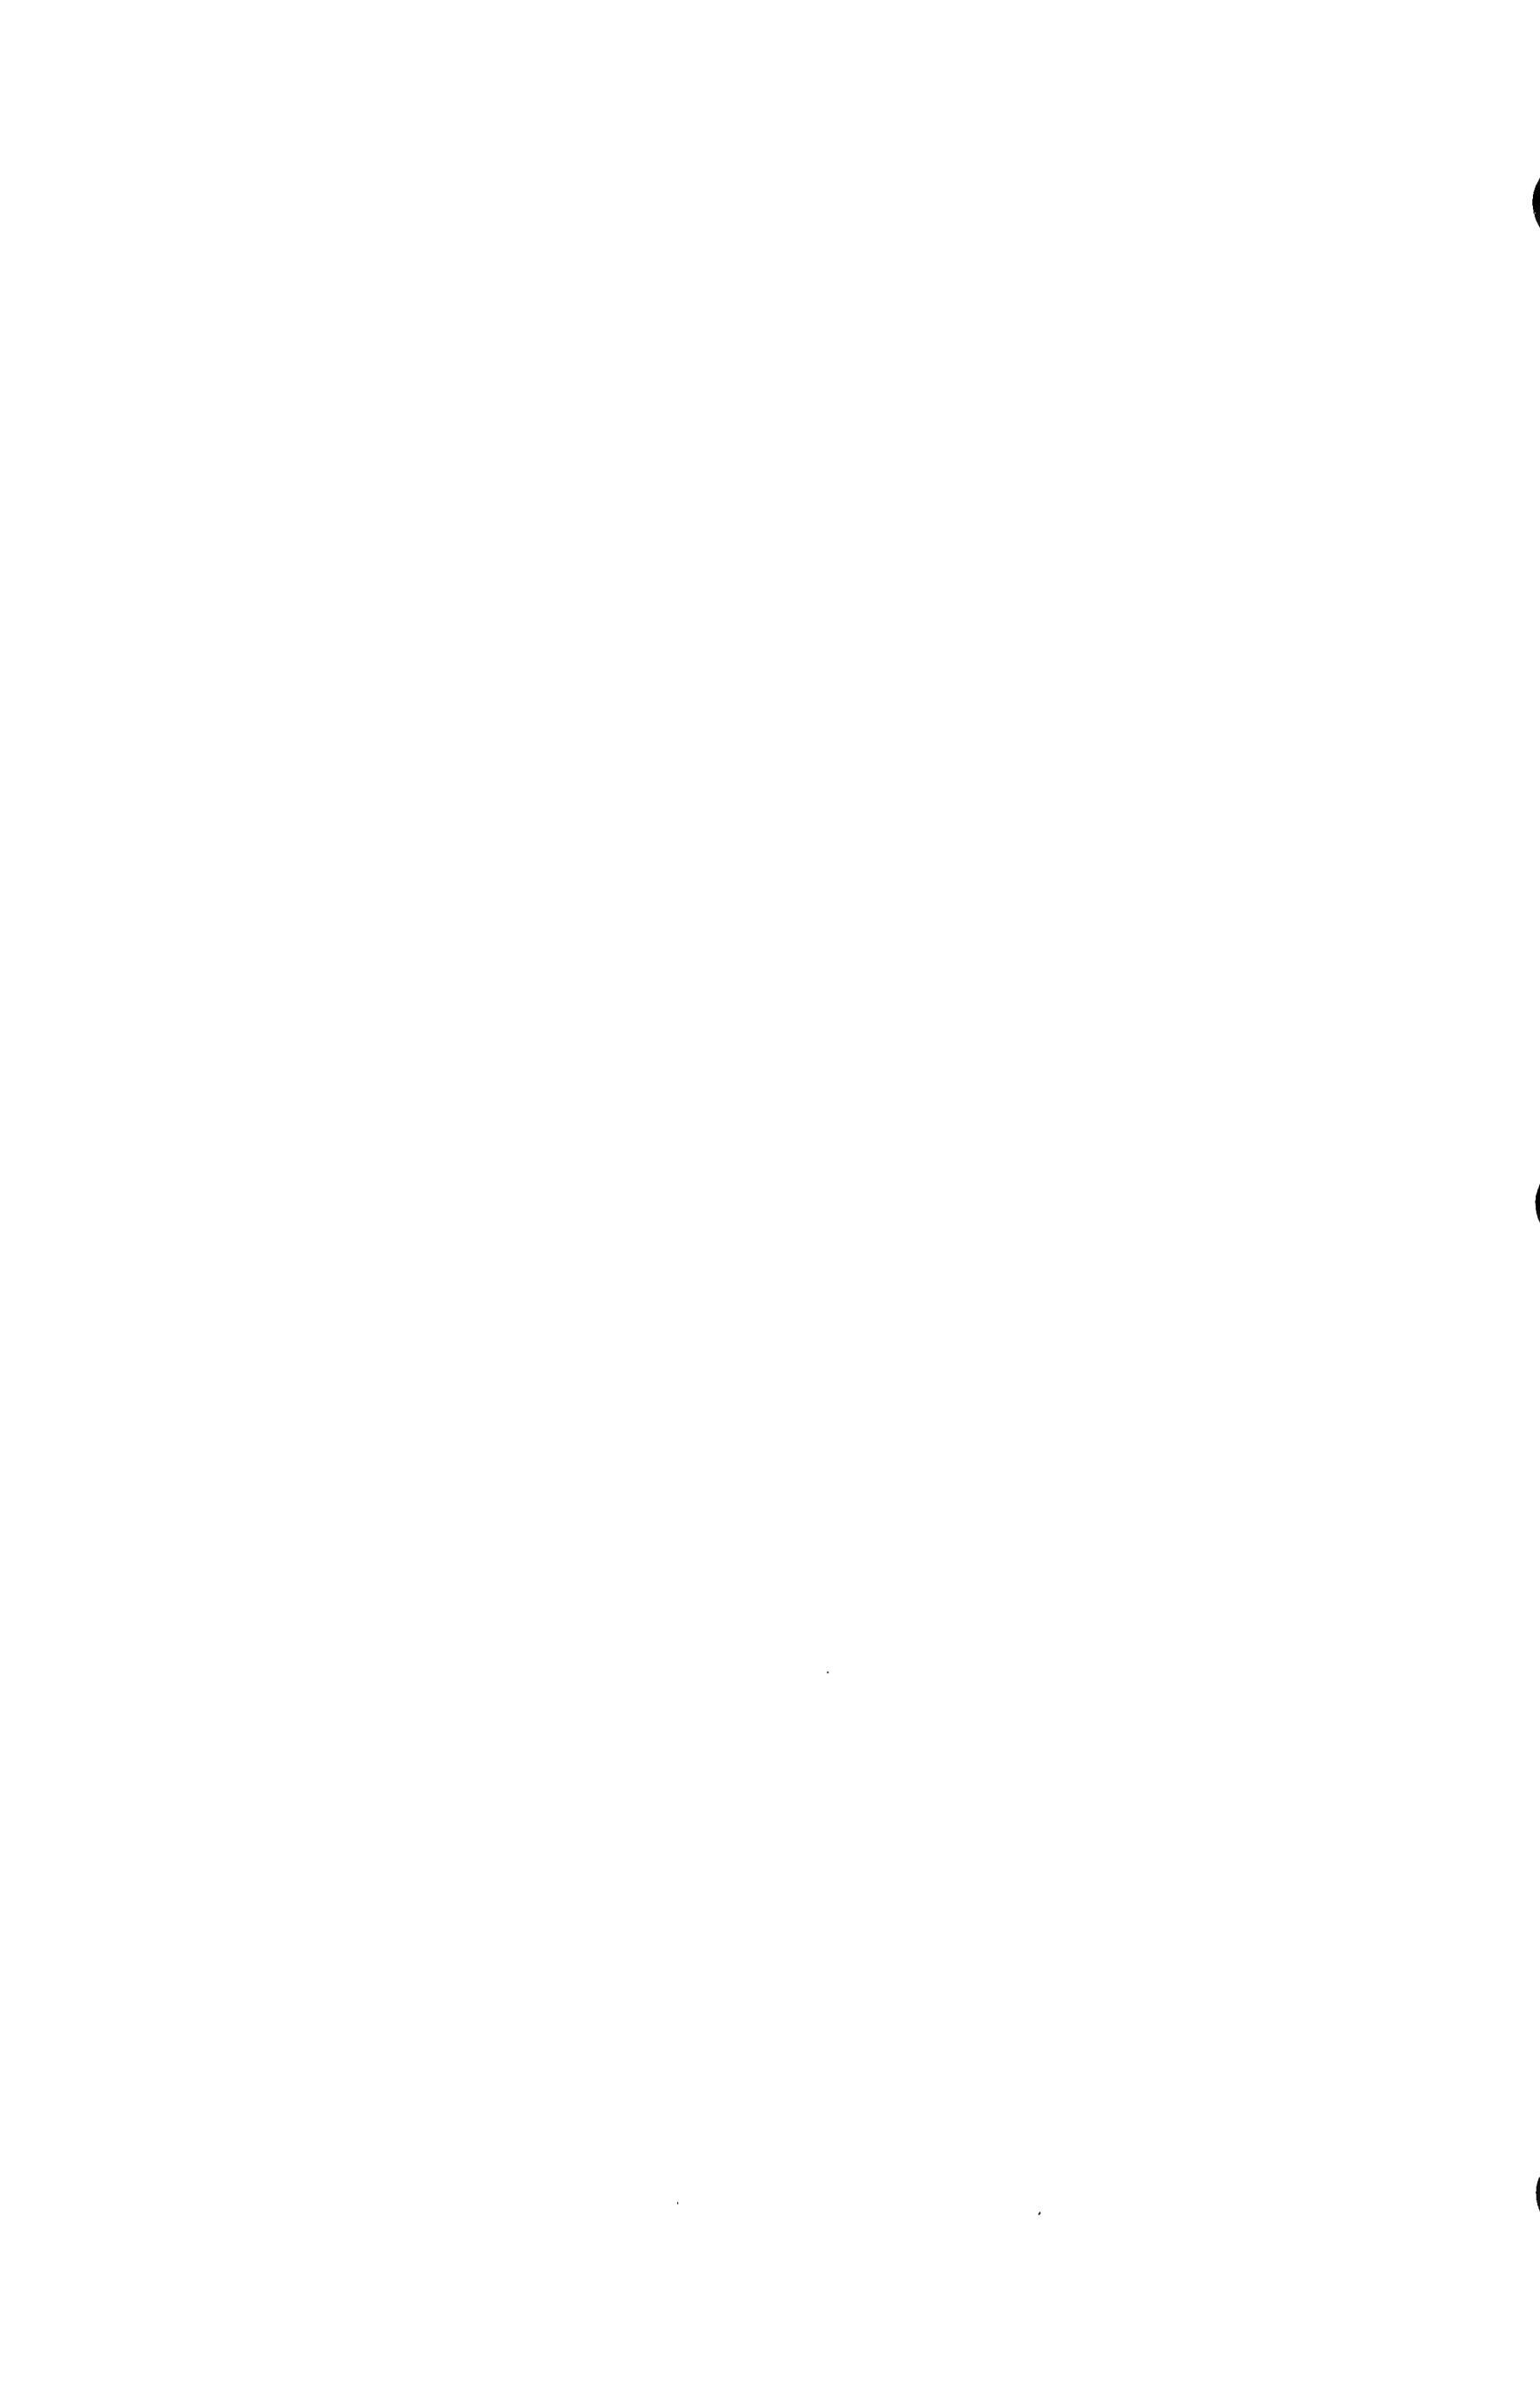

We sat on benches and tiny chairs around "strange little tables" that turned out to be desks! The only free space was in a corner, near the ornal, so we were treated to a stream of hombres. The walls of the school are corrugated metal, and little kids were using a ladder to ascend the wall and peer into the dance hall. We paid 200 colones per male and 100 colones per female to attend, entering through a checkstand of a little table. In one corner was a stand for beer and other drinks, run by ~5-6 men, including Renaldo Aguilas. The place was packed. (see below, 21 June) There were speakers everywhere, such that the benches pounded with music. The banded alternated x 2 fast, Latin beat songs w/ every slow

Greene, H.
1987

20 June
(continued)

"musica romántica." Ticos seem to have two speeds, one of which in comparison to gingos dancing is faster but w/ less lateral movements of the arms and legs - more ritualized. The other is extremely slow, and a strange sort of two-steps. Both my speeds are in between them! The custom is that males ask women to dance, and they rarely refuse. In thoroughly regions like this, Carmen told me, the men tend to be especially pushy and expectant, and to dance especially physically. One couple stood out by their apparel & dancing: he rather typical, w/ shirt open to the waist except for clean dress boots worn over pants like a horseman. She wore a bright red part sint, black boots, and a small black, sort of modified bowler hat. They danced round the whole room, always arms around each other, and the ticos in our group clearly considered them a little unusual. Carmen and I decided independently that she had a certain resemblance in facial features to an Andean Indian. A nice aspect of the evening ^{way} that there was quite a mix — La Selva researchers, ticos and gingos; ticos I knew in past years who live

Greene, H.
1987

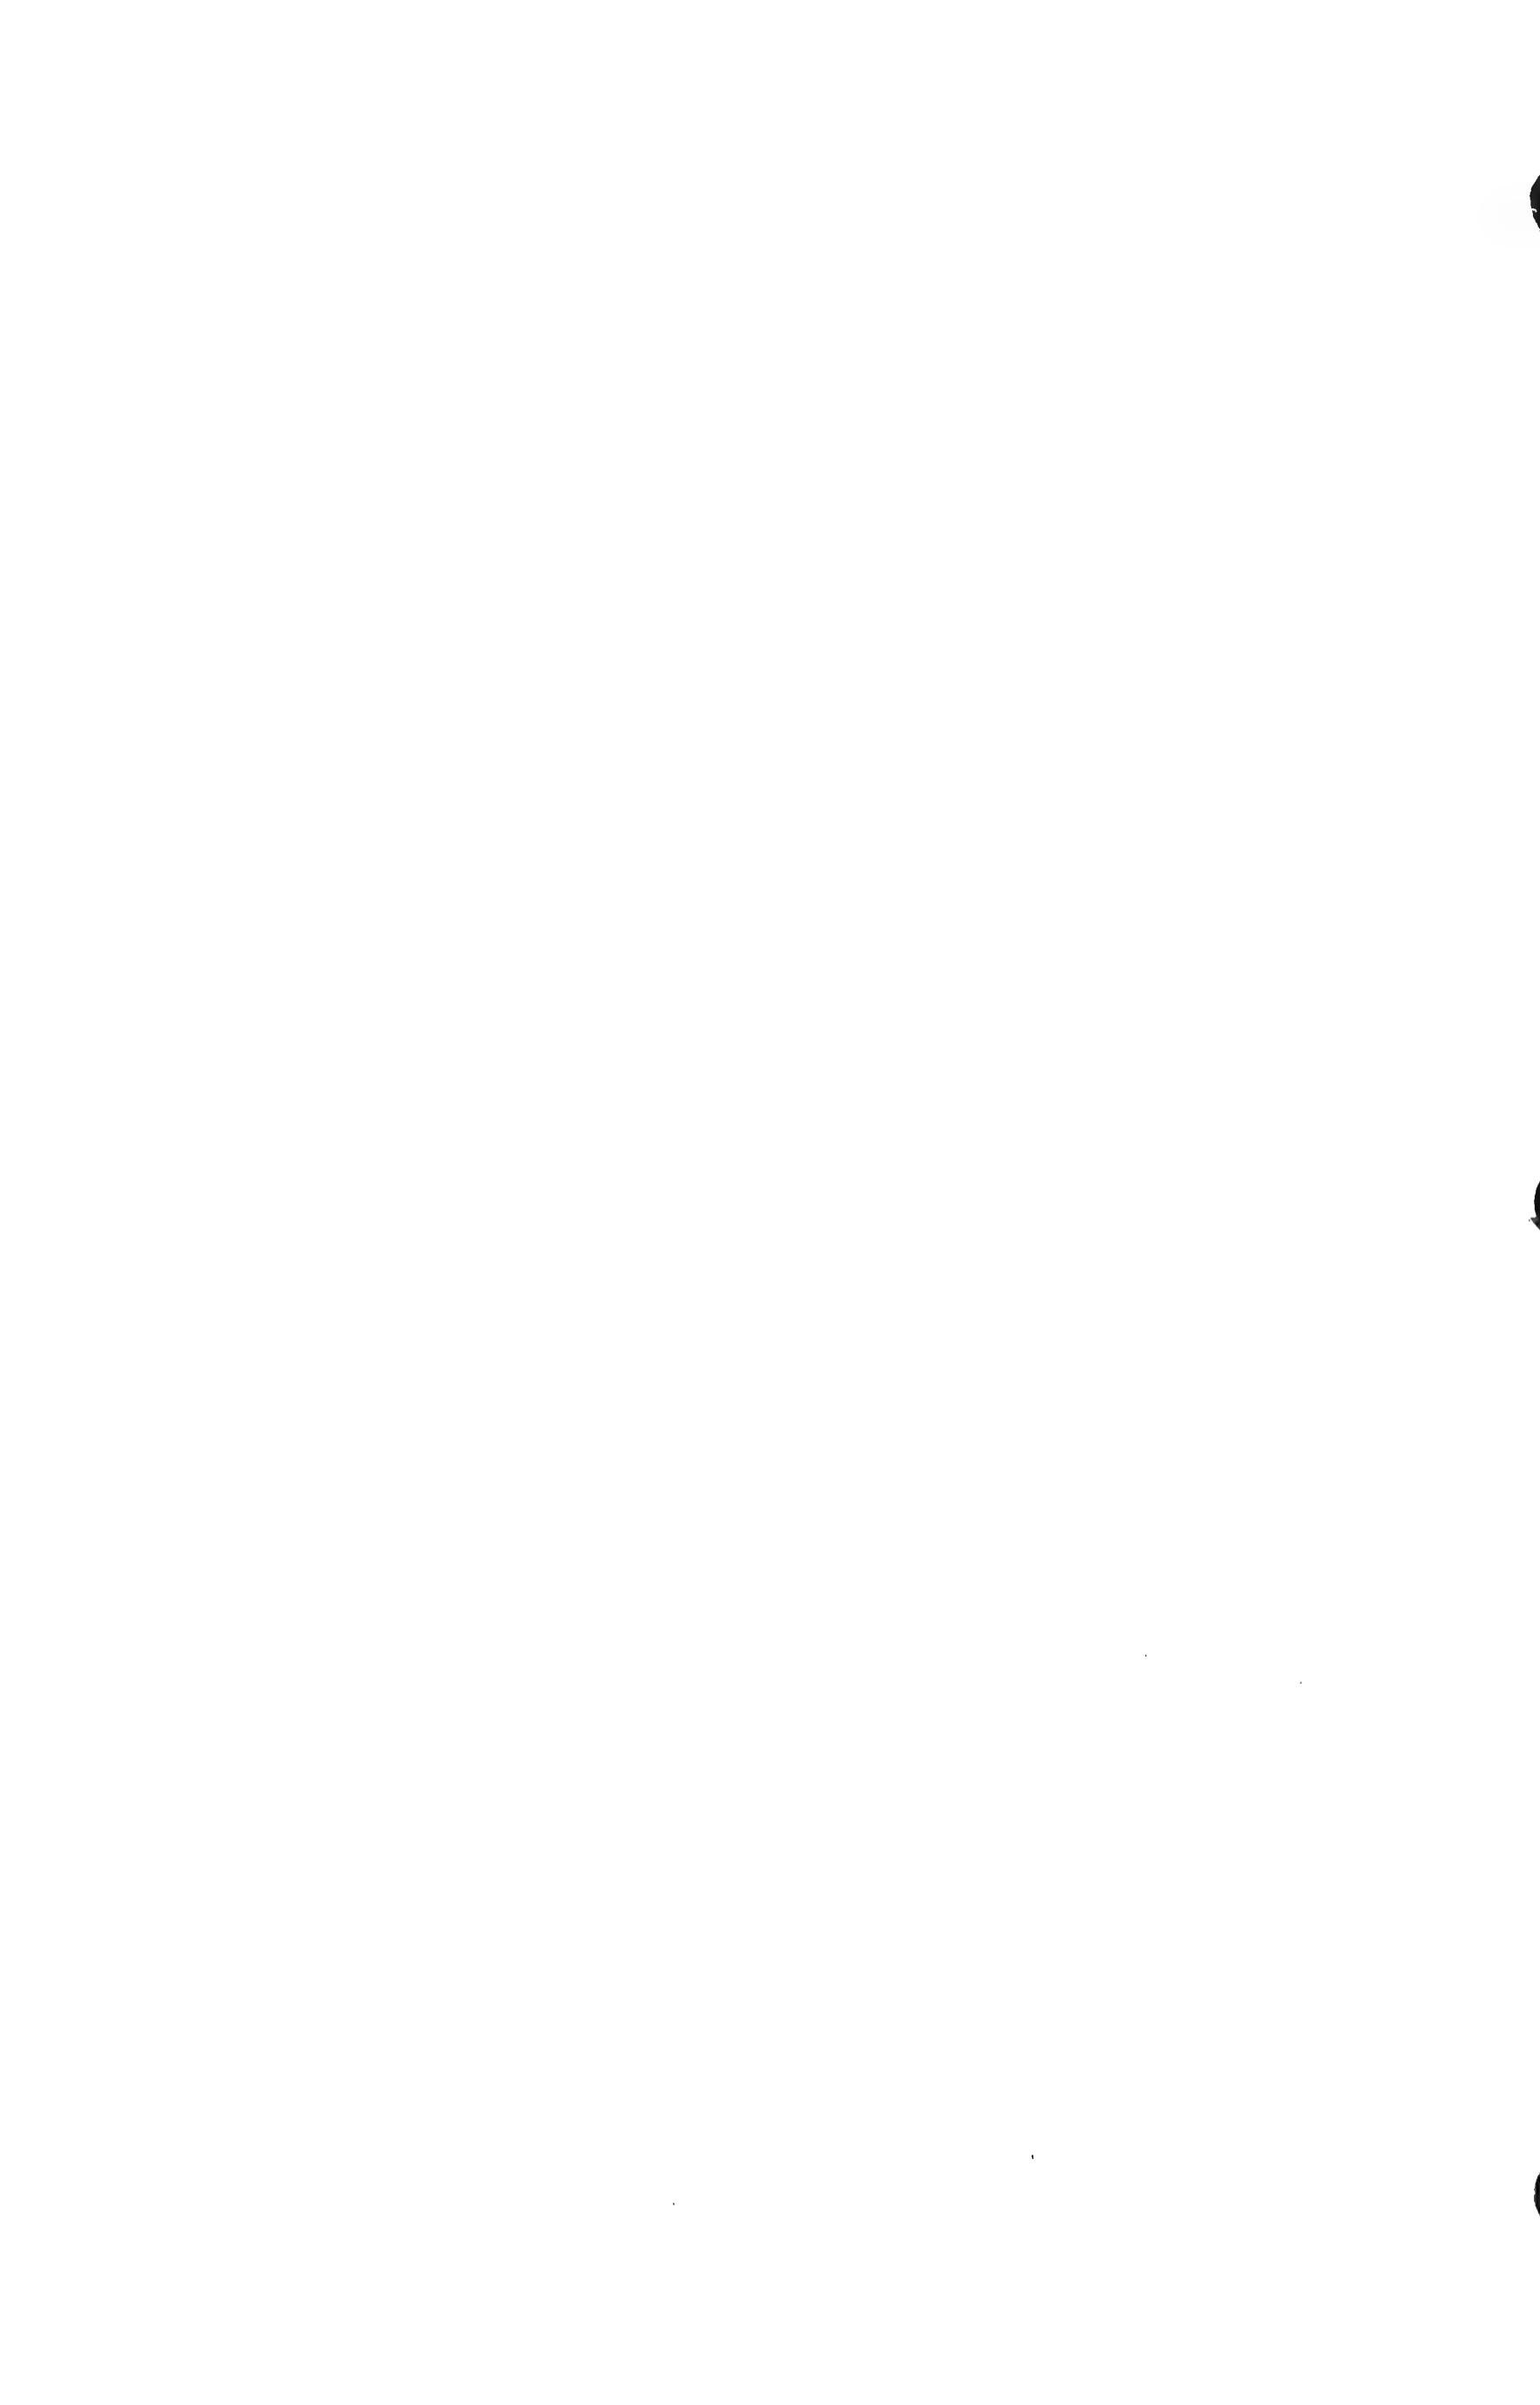

20 June nearly and no longer live at la Selva, like
(continued) Jaime (who was w/ Ricky Van Beikum) and
Freddie (who was w/ Gretchen Braker). park
service personnel, some of whom like Ronaldo
we knew already and some whom we met for
the first time; and local people. Periodically
the band dedicated a song to persons or groups,
e.g., "a Carmen y sus amigos" and ~~to the~~
"a la gente de O.T.S." On the way home,
Roberto Cordero, the station manager who was
driving, and ^{Rocío} ~~Roberto~~ Tópez sang passionate
songs and the windshield fogged periodically.
Finally got in bed, very damp (we were all
drenched in sweat long before the dance
ended), 2000h.

21 June at 20150h Phil Robertson woke me w/ a knock
and the news of a small *Terciopelo* downstairs
by our bathroom. Pulled on pants and
shoes and went down to discover a large
Lepidodeira septentrionalis crawling in a corner.
Perhaps we should rename this species
culeza del baño, as it is the second
such find in a week! 630+189 mm, 55g, ♀.
It's only response to handling was rapid
crawling, writhing, and ejecting a rather foul
smelling liquid from the cloaca. Walking
back across the bridge after a late breakfast,

Greene, H.
1987

- 21 June (continued) I noticed an adult Caiman crocodilus out on a mud bank in partial shade, and numerous Rhinoclemys cf. funerea basking in full sun on emergent tree trunks in the Rio Puerto Viejo. A hot and sunny, partly cloudy Sunday morning! Chatted all afternoon, except for a trip to the water fall. Brief rain in the late afternoon. Checked the Hachis muta at CES 530 at 1929 hr, found it alert under the S. side of the tree, facing S (i.e., towards the fallen log. (Forgot to mention that there were bats flying through the room throughout the dance last night, suggesting to us that it would be a great place for a Halloween Party!).
- 22 June To San Jose this afternoon, including great view of canyons on the edge of Braulio Carrillo.
- 23 June To the "Serpentarium" - Instituto Clodomiro Picado - w/ the O.T. S. class for lectures and demonstrations. Dinner at a nice little french restaurant near the Universidad de Costa Rica, w/ Carmen Rojas.
- 24 June Up at 0530 to drive to Golfito w/ the O.T. S. course. Palmar del Norte, prov. Puntarenas, Costa Rica Stopped here for a picnic lunch in early afternoon, in a little park (w/gazebo) across from the air strip. Saw several adult ♀ and ♂ Gonatodes albogularis active on large trees in the park.

Greene, H.
1987

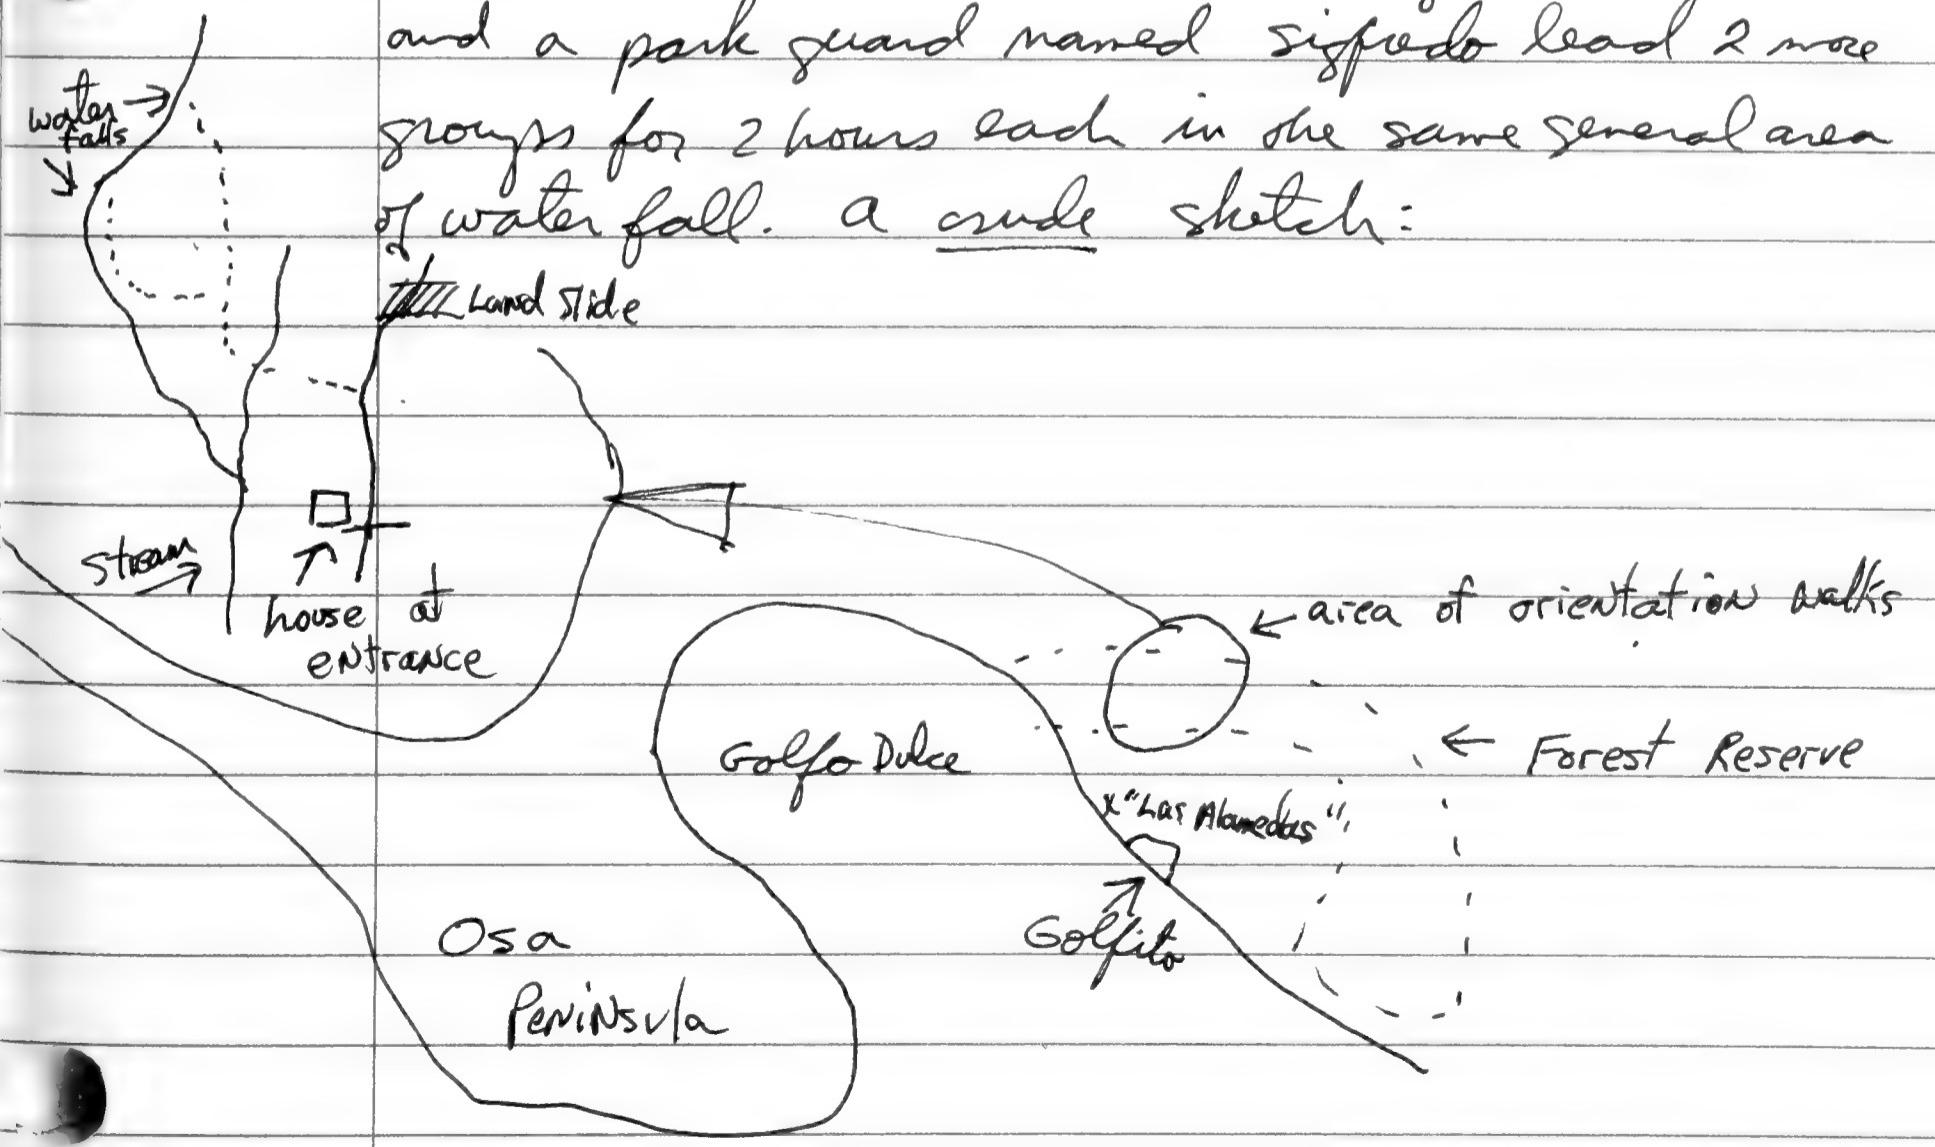

- 24 June Golfito, Prov. Puntarenas, Costa Rica
(continued) arrived here \approx 1530 h, at the field station "Las alamedas," run jointly for the U. C. R. and the U. of Kansas. It consists of the grounds of a former United Fruit Co. operation, right on the Golfo Dulce, and an adjacent forest preserve that apparently is intended primarily as watershed protection. Before dinner, Gene Shupe Bruce Williamson and I took a ride to the top of a ridge above town to see lay of the land. We walked around some kind of relay tower, el. 505 m — great view of steep forested hillsides, the gulf, and in the distance the Osa Peninsula.
- 25 June Pia Paley and I lead to orientation walks for 2 hrs each in an area of second growth and forest edge, NW (?) of town a field km. Drove through cattle pasture, then walked on a mowed track, then walked two trails. Saw only Anolis early in the morning, but later several juvenile and adult Ameiva festiva. Photographed a pretty Eleutherodactylus (cf. regularis?) sitting on the end of a mossy stick, bunched as if conserving water, under a shrub at trail edge in second growth and a few meters from a stream. Got a pentadactyls-like Leptodactylus hiding under large dry leaves nearby. At 0937 h I grabbed a Tortilla melanogaster (236+84 mm) ^{3.99}

Greene, H.
1987

25 June (continued) as it crawled off trailside into leaf litter. Only reaction to handling was to squirm. Walked to a fine waterfall \approx 1030 hrs. Multiple cataracts over a broad vertical rock face, maybe 10m high, w/ a pool at the bottom. We saw two juvenile Basiliscus basiliscus in vegetation and wet rocks, \approx 2 m above the pool, and 2 juvenile Bufo haematiticus on wet, mossy boulders at poolside. Morning was hot and sunny, by 1430 it is overcast.

26 June The routine here is up \approx 5:45 for breakfast at 0600, then begin activities at 7 AM. Today Pia and I and a park guard named Sipedo lead 2 more groups for 2 hours each in the same general area of waterfall. a crude sketch:

Greene, H.
1987

26 June (continued) Saw only Anolis and Ameiva on the trails, and several juvenile Bufo haematolicus around the big lower waterfall. afternoon and evening devoted to indoor exercises and lectures.

27 June Pia and I lead a field problem on observational study of behavior in the general region of the waterfall. We watched a Rhamphastus swainsoni casually and did focal animal and instantaneous sampling on Anartia fatima butterflies in an open stretch along the main stream, and on 2 juvenile Basiliscus basiliscus at the waterfall. Again saw Anolis and Ameiva on the trails, and Bufo haematolicus on wet rocks among moss, at the waterfall. Indoor activities in the afternoon & evening.

28 June a repeat of yesterday's field problem, w/a different group. Nice long shower in the afternoon. Indoor events afternoon and evening.

29 June Students are doing group projects w/out us.

One of our drivers brought me a Stenocershina degenerhardtii found on the road at the NW edge of Golfito, still alive but w/a broken neck at ≈ 0800 hr. (77g, 510+122 mm, photographed).

30 June Left Golfito at ≈ 0830 hr., arrived in San Jose in a driving rain ≈ 1430 hr, w/only a stop for diesel fuel. Just me and the driver, Mauro Fonseca, who told me there's lots of communism around Golfito and that our President Reagan doesn't like the poor.

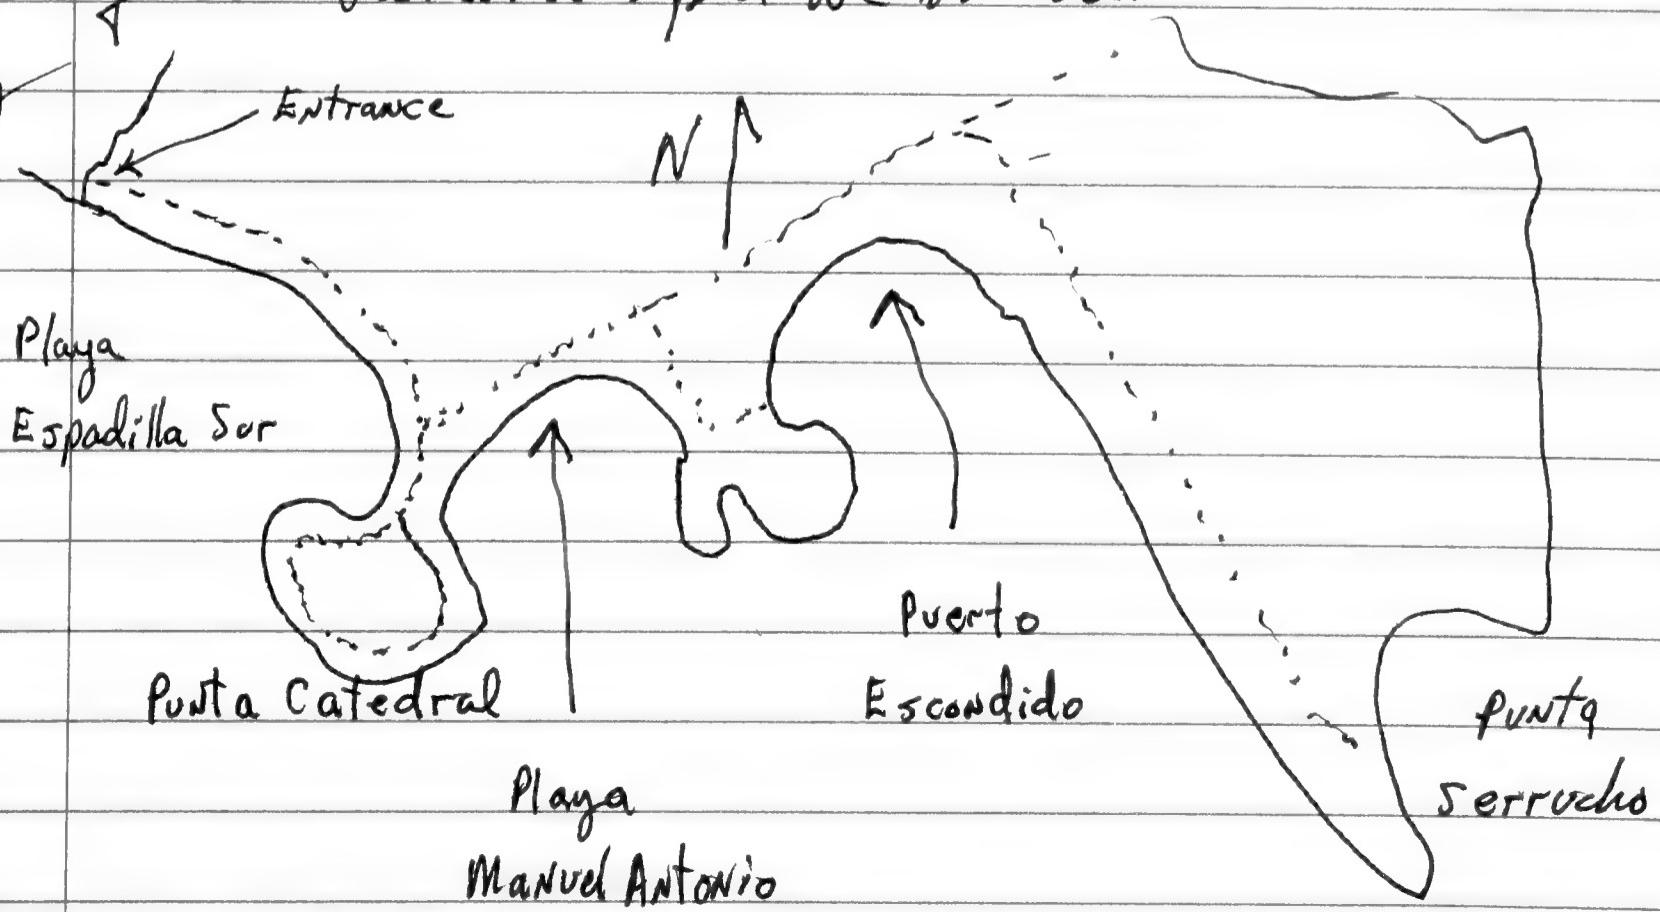

Green, H.

1987

1 July

Parque Nacional Manuel Antonio, Prov. Puntarenas, Costa Rica
arrived here and took a room at the Hotel Manuel Antonio at \approx 0900 hr, after a fast and uneventful flight on "Sansa" to Quepos. w/ Beth Newell, a Stanford U. postdoc who works at La Selva, and we initially had some confusion over a room because we wanted two beds - finally ended up for the same price in a room ~~w/~~ w/ four beds. Went for a walk into the park, which basically consists of four bays w/ beaches and the adjacent forest. After a rest we went NW from the hotel along a road that parallels the shore. Saw several juvenile Ctenosaura sunning on the road and nearby rocks, and a couple of Anolis (not festivus - A. quadrilineata?), and one smallish adult (?). A fine dinner of fish, ceviche, and a giant quasi banana split we shared.

2 July

Akene, H.
1987

2 July (continued) We left \approx 0830 for the park, intending to walk to Punta Serrudo, \approx 2.5 km. Learned at the headquarters that we couldn't use that trail until 11 AM (use is timed to low tide because of dangerous currents). Instead walked the trail around Punta Catedral, which took \approx an hour.

Nice forest, tho we saw only Aneiva (cf. festiva) and Anolis, and literally hundreds of spectacular land crabs - dark red-brown carapaces, bright orange legs and yellow eyes (or at least eye spots).

Sitting on the beach at the end (i.e., Playa Manuel Antonio) we watched a very healthy looking, large male Ctenosaura similis ambly along the forest edge, frequently seizing some whitish object (fruit?) from the leaf litter and swallowing it w/ a few jaw movements. At 1100 we entered the trail to Puerto Escondido, which winds through forest then emerges after a steep slope onto a rocky beach. Whole loop took us 2 hours, including the time spent being lazy on the beach. Late this afternoon we went back to Playa Espadilla Sur to swim (best waves) as a thunder storm came in.

We got back before it hit at \approx 1600 hr, and watched a tremendous two hour downpour from the balcony of the Hotel Manuel Antonio.

(see below)

8 July Up early and to the "airport" for the Sansa

Greene, H.
1987

4
3 July
(continued)

flight to San Jose. at the airport we saw a Beachcraft (?) under guard w/ flat tires, and later read in the newspaper that they had been shot out in an enormous cocaine bust. Uneventful flight and back to the Hotel Galilea and breakfast in San Jose by 10AM. Shortly after I started out and ran into Dan Janzen, then had a visit w/ him before going to lunch w/ Beth. While having coffee at the Parisien cafe, we met unexpectedly Mike and Patricia Fogden, on their way to the states.

3 July Forgot this day, which we took lazily. Went back to Puerto Catedral and photographed crabs. Saw one that had been partially eaten.

5 July Caught a 9AM bus, had a terrific view of Brabilio Carrillo N. P., then a long, slow trip via Rio Frio and arrived at La Selva in time for a late lunch \approx 1:30. At 1616 hr I found the subadult Lachesis muta under the Danaea fern, just as I last saw it two weeks ago! Earlier, \approx 1400h, watched two Lutra longicauda hunting in the Rio Puerto Viejo, from the La Selva bridge. They dove frequently, seemingly searching undersides of partially submerged logs. At least twice one of them caught some sort of large crustacean,

Greene, H.
1987

9 July
(continued) large enough it seemed to more than fill the mouth, and the carapace of which could easily be heard cracking from up when we stood. Once we could clearly see that the legs were removed, seemingly by either throwing or slamming against the log or both. Two large trees a few tens of meters apart were searched in less than 10 minutes, and at least two prey were caught at the second. The two seemed to hunt independently, but several times mutually approached and contacted each others' heads.

6 July a cloudy, drizzling morning - rain supposedly started \approx 0100 hrs. I actually thought of getting a blanket during the night. Checked the Lachesis muta at CES 530 at 1600 hr - under Danaca.

7 July Overcast w/ sunny spots. Walked out to Holdridge 225, where yesterday Rodolfo saw a Bothrops asper on the trail. Saw it at 0815 hr, loosely coiled on the trail at E edge (successional plots), facing into the trail and seemingly asleep. Took pictures. It is an adult, perhaps 1.5-1.7 m total, brown and gray, and very skinny. Judging from length and tail shape, it is a female and perhaps recently gave birth. Walked back to the CCL and went around the loop. Missed what was either a Dendrophidion or a juvenile Mastigodryas when it dashed under the boardwalk at \approx 0840. at 0859 hr, CCL 950m,

Greene, H.

1987

7 July
(continued)

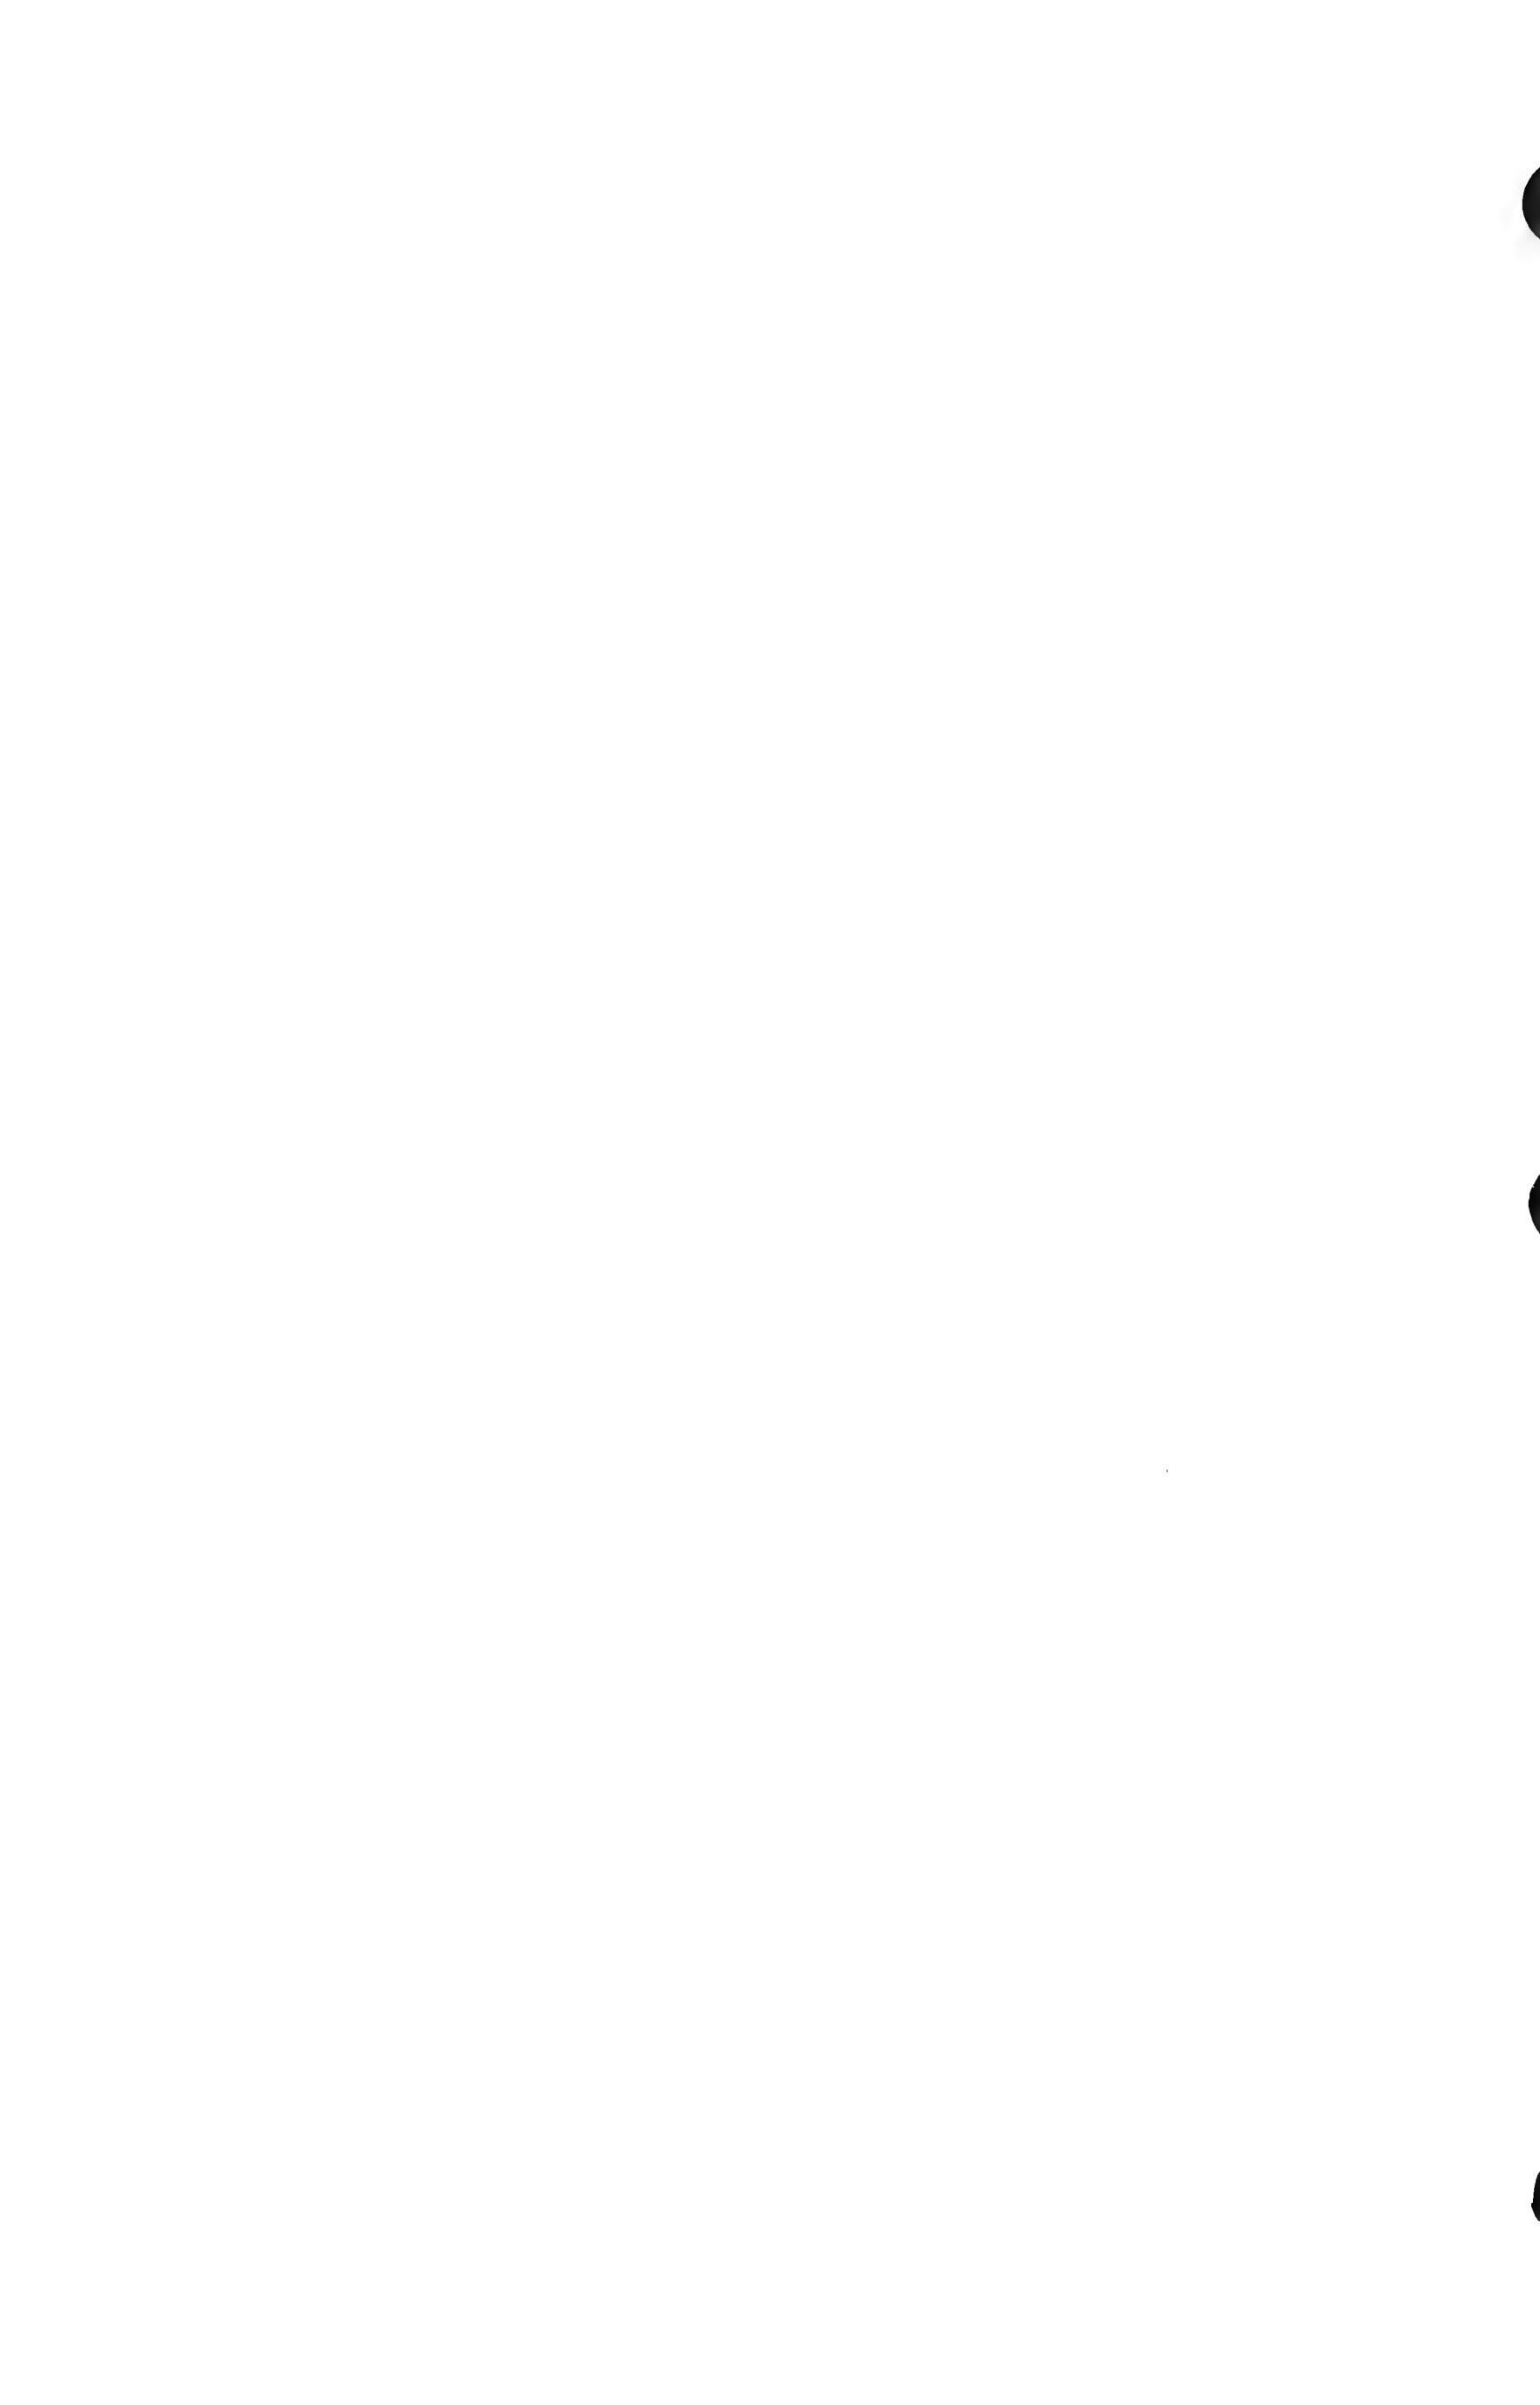

I snatched a Leptophis ahaetulla as it lay immobile in shade on the trail. Do they freeze as one approaches? It is a gravid ♀ (4 eggs), 840 + 535 mm, 81g. Thrashed, gaped, and cloacal discharged while handled, and glided quickly away when released into foliage.

at 0947 hr found the Hadesis muta at 530 CES, under the Dansea fern. at 1930 hr.

Mauricio called me to a snake crawling into leaves of a Heliconia plant in front of the AC lab, which turned out to be a very large Leptodeira annulata. It thrashed, spread the quadrates, and ejected a small, slightly cloudy fluid from the cloaca (570 + 152 mm, 95g, no food, gravid female). Rained most of the afternoon and into the evening, and I saw several juvenile Bufo marinus while walking back to the cabina after dinner. I wonder if L. annulata is more an edge species than L. septentrionalis — and what about the Bufo? I have found B. marinus here in deep forest, but perhaps it has to move to more open areas to breed ...

8 July

at ~0800 walked out to Holdridge 225 to check the Bothrops asper, w/ Rob Colwell and Ann Greig. Yesterday Anna and her sister Nancy had twice walked w/in a meter or less of the Tercioselo w/out seeing it. This morning we met Bev?

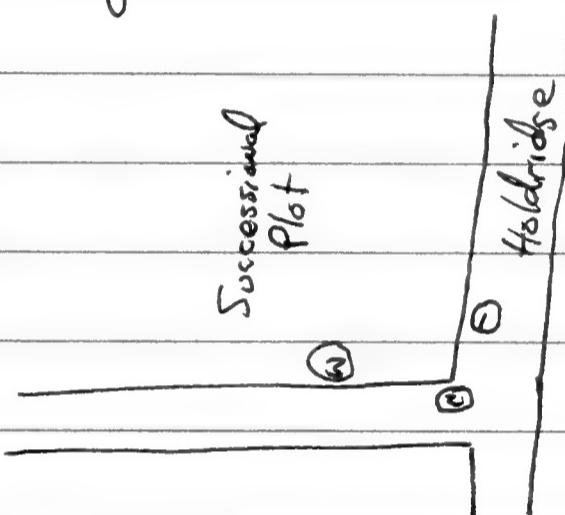

Greene, H.

1987

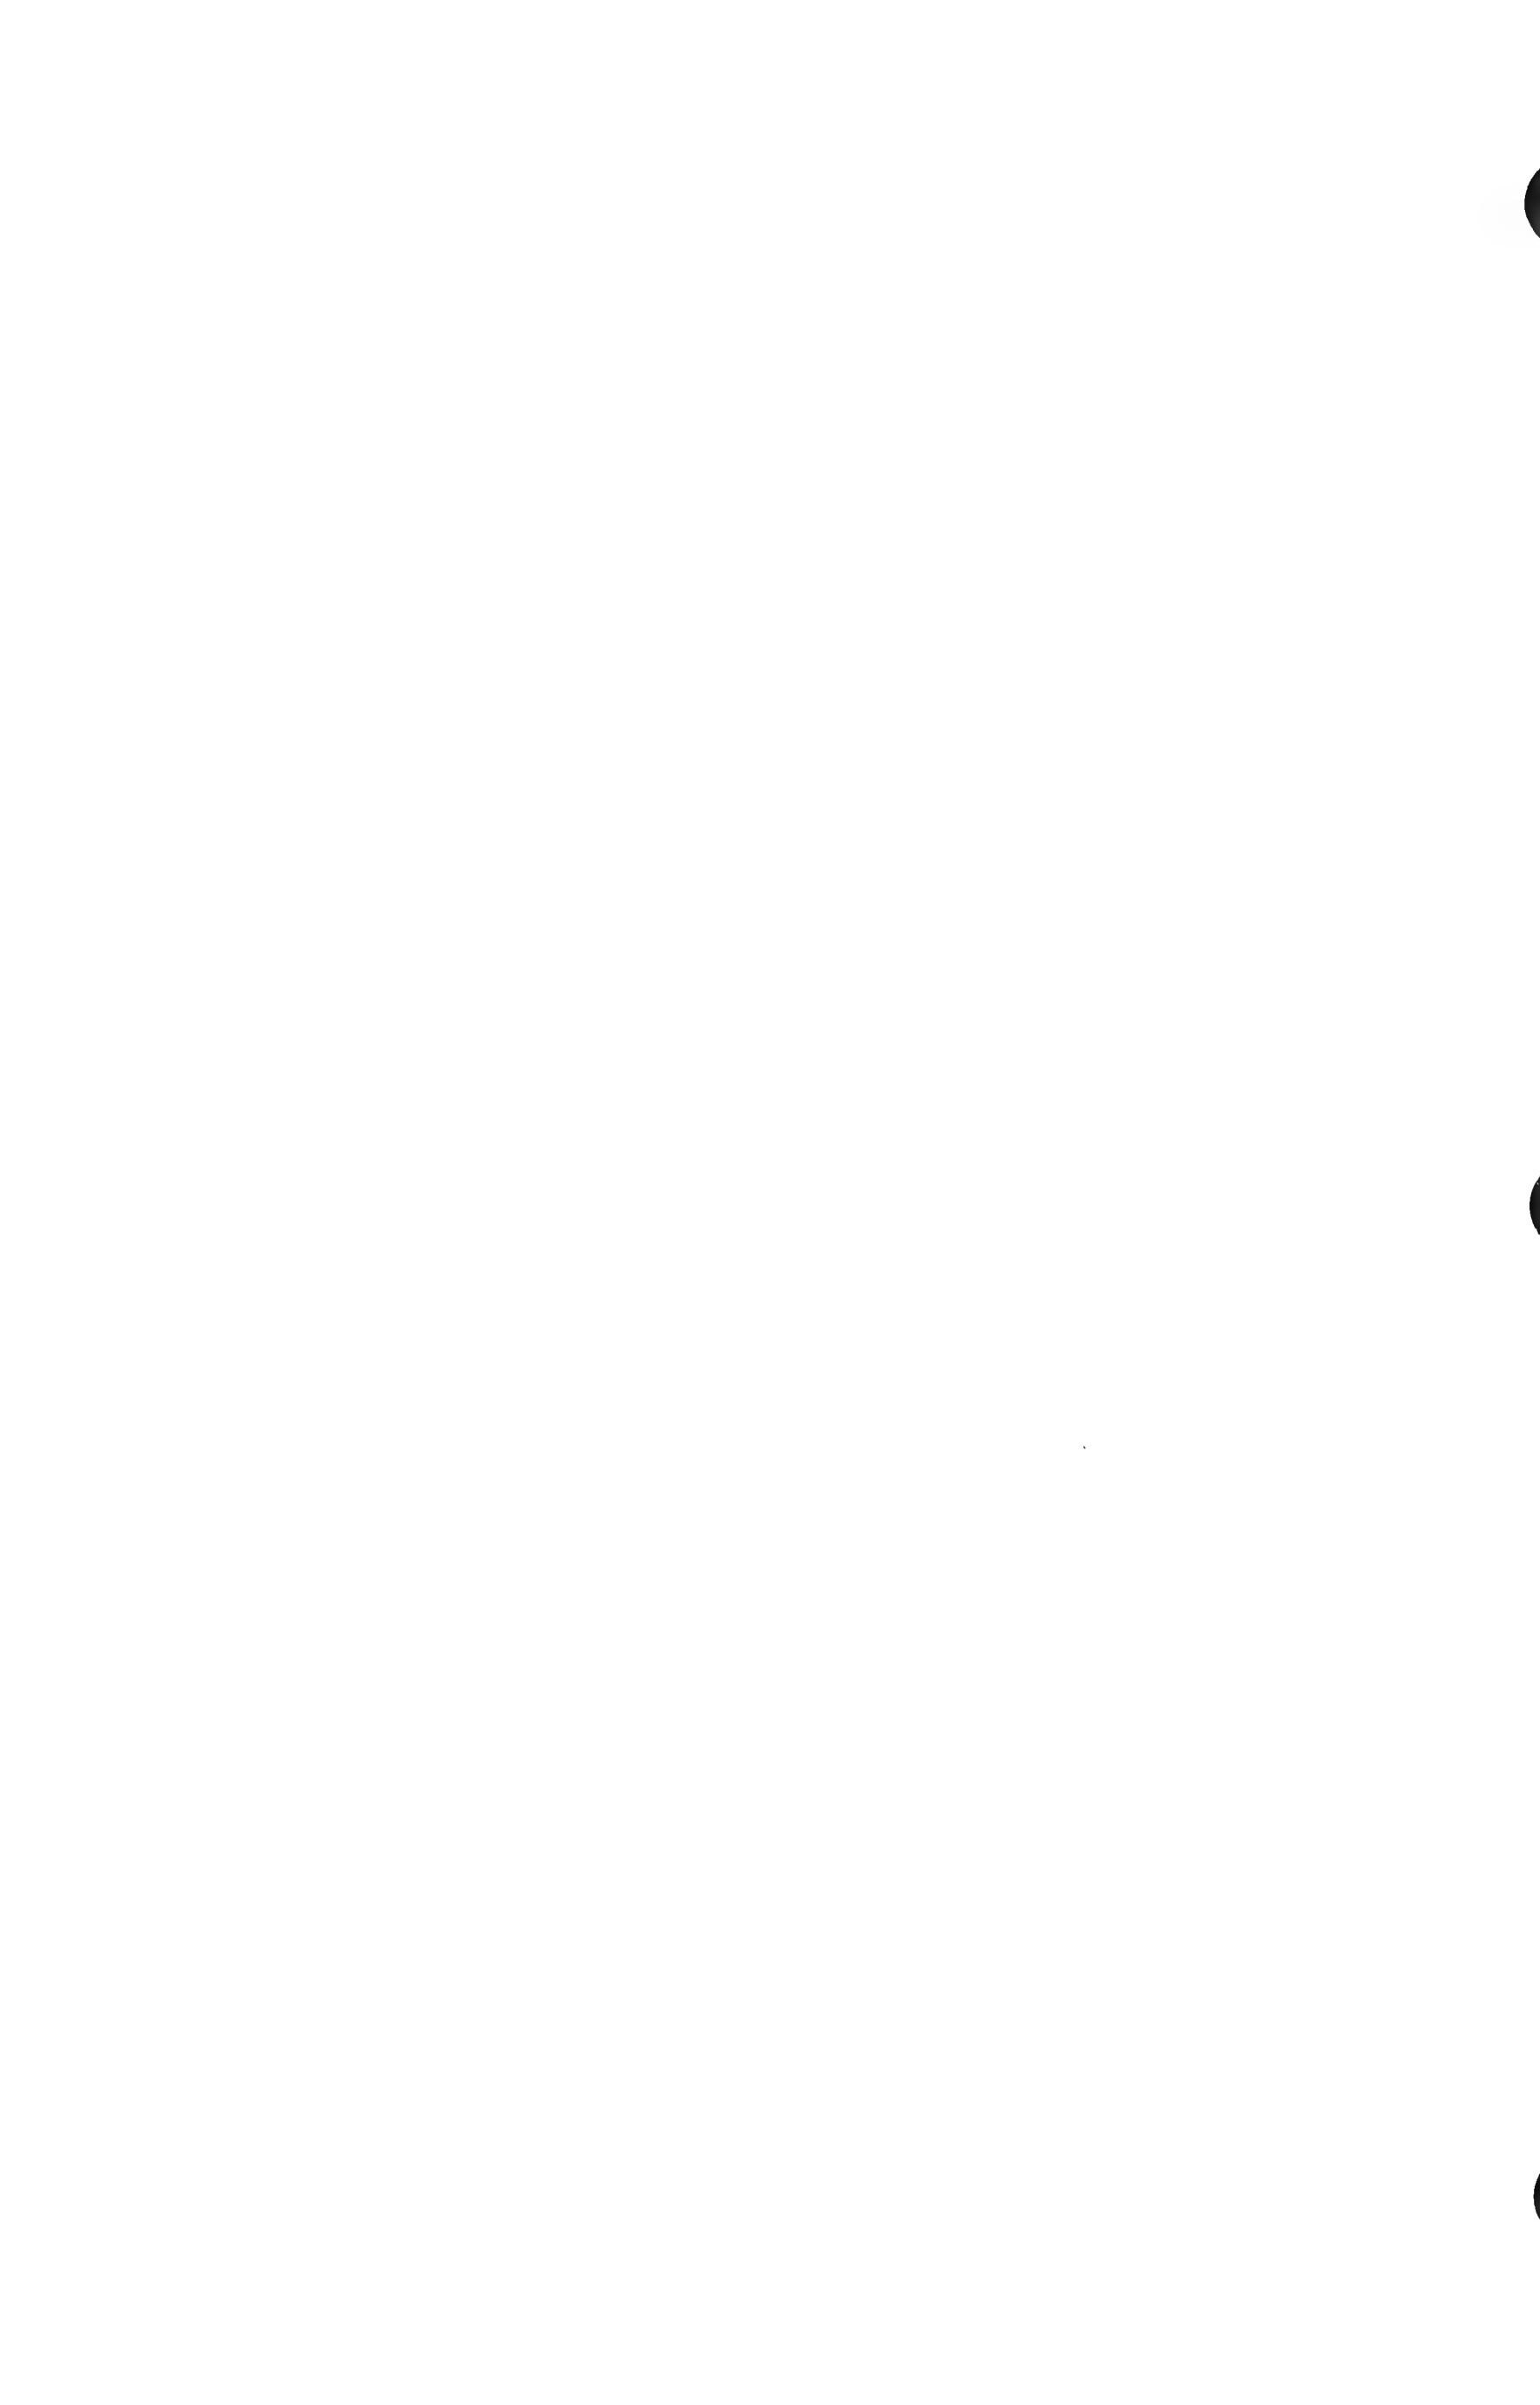

8 July
(continued)

a Canadian, who had just seen the snake, but when we all arrived the snake was gone. Rev had seen it 10 minutes earlier, ≈ 2 m from where I spotted it yesterday. Looked around and found the snake just into a successional plot and loosely coiled, ≈ 1 m from where she saw it.

- ① = 1st sighting
- ② = Rev's sighting
- ③ = last sighting

Started raining as we walked out, and continued all morning. Rain slowed, then ceased in early PM. At 1515 hr. the Lachesis muta was coiled under the Danaea fern at 530 CES; for the first time I have the distinct impression from overall girth and exposed skin between scales that it has eaten. At \approx 2045 hr went back w/ 3 students from the OTS course (which arrived today) and found the Lachesis in the "hunting spot," facing the fallen tree. Its head and neck were in an S-coil, but the head was not at all raised and was w/in the outer body coil. We did not linger nor disturb it, but I did not get an impression of a food lump. Rained all evening.

Greene, H.
1987

9 July

Sunny, partly cloudy, hot by mid-morning.
Walked out to 225 Holdridge, and found the
Bothrops asper still in dense vegetation, just
off the path next to the successional plot ("3" on
previous page). I gently lifted a blade of grass
for a better look, and the snake moved its
head slightly. Judging from Alejandro Solognano's
data, this is too early to be a spent female
- so I wonder why she is doing so poorly? If
for whatever reason, she is starving, it is an
interesting counterpoint to my notion of large
vipers as not generally having intense energy
problems. At 0945 hr checked the hachis mata
at CES 530, and found it under the Donaea
fern - and not, today, seeming impressively
fullsome. w/ respect to Leptodeira annulata,
I was thinking this morning about the fact that
it is a stocky spotted snake, yet repeatedly
tried to escape by crawling - a contradiction to
Jackson et al.? The point is, it didn't escape
that way, whereas a striped or unicolor
Mastigodryas would likely have succeeded.
Just after lunch (1240 hr) I was summoned that
there was a large snake on the bridge - ran
over to see a Spilotes pullatus descending
slowly a Gecropia tree, so I hung over
the edge and grabbed it by the posterior.

Greene, H.
1987

9 July (continued) By the time I stood up it was chewing fiercely on my pants legs. Carried it back to the mess hall to show students. Even when held by the head it readily tried to bite an approaching finger. When I released it on the ground it inflated the bulbous throat and inflated/vertically flattened the foreparts, and moved them to orient to a person moving nearby. At one point it turned and when I stood up seized the crotch of my jeans.

Much of the time I was handling it the snake rapidly vibrated the posterior 200-400 mm of tail. Although I only noticed one small blob of cloacal contents, it ejected a mildly strong and mildly offensive odor, which clung to my T-shirt for sometime thereafter. This morning R. K. Colwell and a group of O.T.S. students were in the Ecological Reserve Swamp, on the Sendero Cantarana, when they observed a Hemiphractus semiplumbeus fly off w/ an Agalychinis callidryas. This was during a dense daytime breeding aggregation of these frogs.

10 June At \approx 0830 h Gene Shoops found a small Bothrops schlegeli ($413 + 70$ mm, 30 g) coiled on a bromeliad at the end of a small limb, \approx 2 m above damp mud on the w edge of the swamp in

Greene, H.
1987

10 July
(continued)

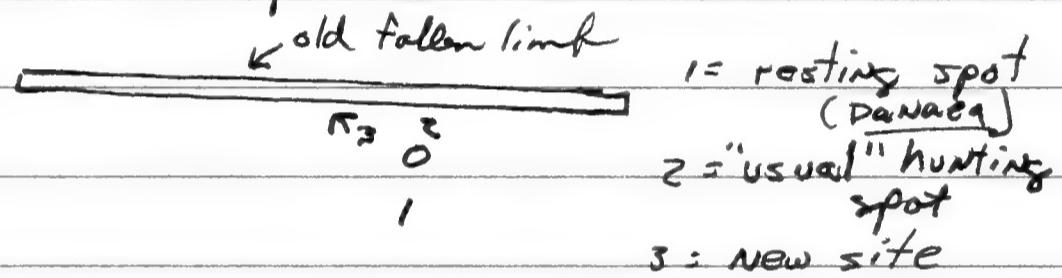

the Ecological Reserve, beside the Sendero Cantarana boardwalk. He perceived several prominent protrusions suggesting multiple prey items. I caught the snake ≈ 1400 , at which time there was a single, large, \approx fusiform bulge. At ≈ 1845 hr I palpated a bat (165g, one wing largely digested) from the snake. Seems that the bat was eaten early this morning, perhaps as it returned to a roost that had previously been located by the snake chemoreceptively. At ≈ 1500 located an adult Hadesis muta at CCC 700 that Joseph Connell told me about. The snake is ≈ 2 m long, healthy and fresh shed looking, and ≈ 20 m off the trail behind an old fallen tree. The snake was near the base, lying on a ledge of soil under the edge of the log, quiescent.

Rained heavily as we walked back in and out to 530 CES, where the smaller H. muta is still under the Dancea fern. Both Dave Hardy (who of I am late arrived today) and I thought it might be in pre-shedding condition. Rain continued into the night.

11 July Partly cloudy, some sun. Walked around the Camino Circular, and found the H. muta at CCC 700 as was yesterday, except head had changed positions. Checked the Bothrops asper at Holdridge 225, and found it in

Greene, H.
1987

11 July same place as before ("3") and still alive - it moved the head slightly when I moved a nearby leaf w/ a snake hook. Dave Hardy at first thought it dead, for good reason - the mouth slightly agape, seemingly w/ a little dirt in it. At \approx 2030 hr found the Hadesis muta at CES S30 out "hunting", \approx 30-50cm to the side of its tree; a new position:

It's ~~leg~~ head was aimed at an angle to the rotten limb (3, arrow).

12 July Left at 0800 and walked the CCC, out CC, across the CS and back in on SHO & SOC. The Hadesis muta at CCC 200 is in the same place but its head now is easily visible & facing out. When I got fairly close for a photo it flinched. Saw cat tracks, possibly Felis pardalis, on the eastern edge of the Sendero El Guanapo in two places several tens of meters apart and traveling west - none on the Holdridge, although there were several muddy places where we might have picked them up. Found the Bothrops asper at Holdridge 225 at the same place but a few cm further into the vegetation

Greene, H.
1987

12 July and harder to see. I did not disturb it and
(continued) saw no movements. Walked out the CES to check
Lachesis muta at 530m - asleep under the
Danaea - and caught a green/lichenose
Norops capito near the ground on a green
trunk sapling next to the 200m marker.
Partly cloudy, no rain, river way up.

13 July Left at 0800 hr w/ Dave Hardy, Ian Tate, David Carr
(U. Maryland) and Joe Bernardo (Duke U.). Checked the
big Lachesis muta at 700 ccc, and found it concealed
under the opposite side of the fallen log (trail
side). The Bothrops asper at 225 at Holdridge
was dead, limp, and only slightly smelly - few
bugs. It weighed 760g, 1530+235 mm♀. Dissected
it later and found general emaciation - no fat,
organs and somatic musculature seemingly
reduced. There were several large, pale, slender
worms on the surface of the lung (sawed -
acanthocephalans?). Dave found that one
mandible had a fracture healing poorly, i.e.,
slippage of the parts possible. We surmise that
maybe she starved because of the injury, perhaps
exacerbated by the parasites? Earlier, at 0856 hr,
I grabbed a \approx 1.6 m Pseustes poecilonotus at
ccc 450 as it crossed the trail. It tried to
crawl, then bit fiercely. Only got the full
defensive display by holding it by the tail

Greene, H.

1987

13 July
(continued)

while Dave Hardy poked it w/ an umbrella. Then it inflated the neck, spread the quadrates, gaped widely and struck repeatedly. Bit whenever it contacted on the sticks. At 0932 hr grabbed a Dendrophidion percarinatum ^{3 eggs} ^{638, 582 + 421 mm} ♀ at SHO 440 m - it crawled frantically, seemingly inefficiently, and thrashed and inflated the body when seized. Inflation caused light skin to appear, but not dramatically blue as in D. vittatum. Checked the camp on the Sendero Sabalo-Esquira where in \approx 1982 Manuel Santova and I found 2 Bothrops asper, but no snakes. at \approx 1980 m on that trail we found an adult gravid ♀ B. asper where Gene Schoop spotted her yesterday. Site is a huge tree fall that cascades down a steep slope to the trail, which is bounded on the East by the stream. There is a huge pile of sticks (branches) at trailside, and the snake was in a loose coil at \approx 1.5 m about trail and facing it. Dark rich brown, w/ a very yellow head and white chin. During \approx 10 minutes in which the four of us milled around its only response was an occasional tongue flick. One of the most impressive snake scenes

Greene, H.
1987

13 July (continued) I have seen here! Up to this point it had been partly cloudy w/ frequent bright sun, but as we started back ≈ 1020 hr, a hard rain started that didn't really let up til after lunch.

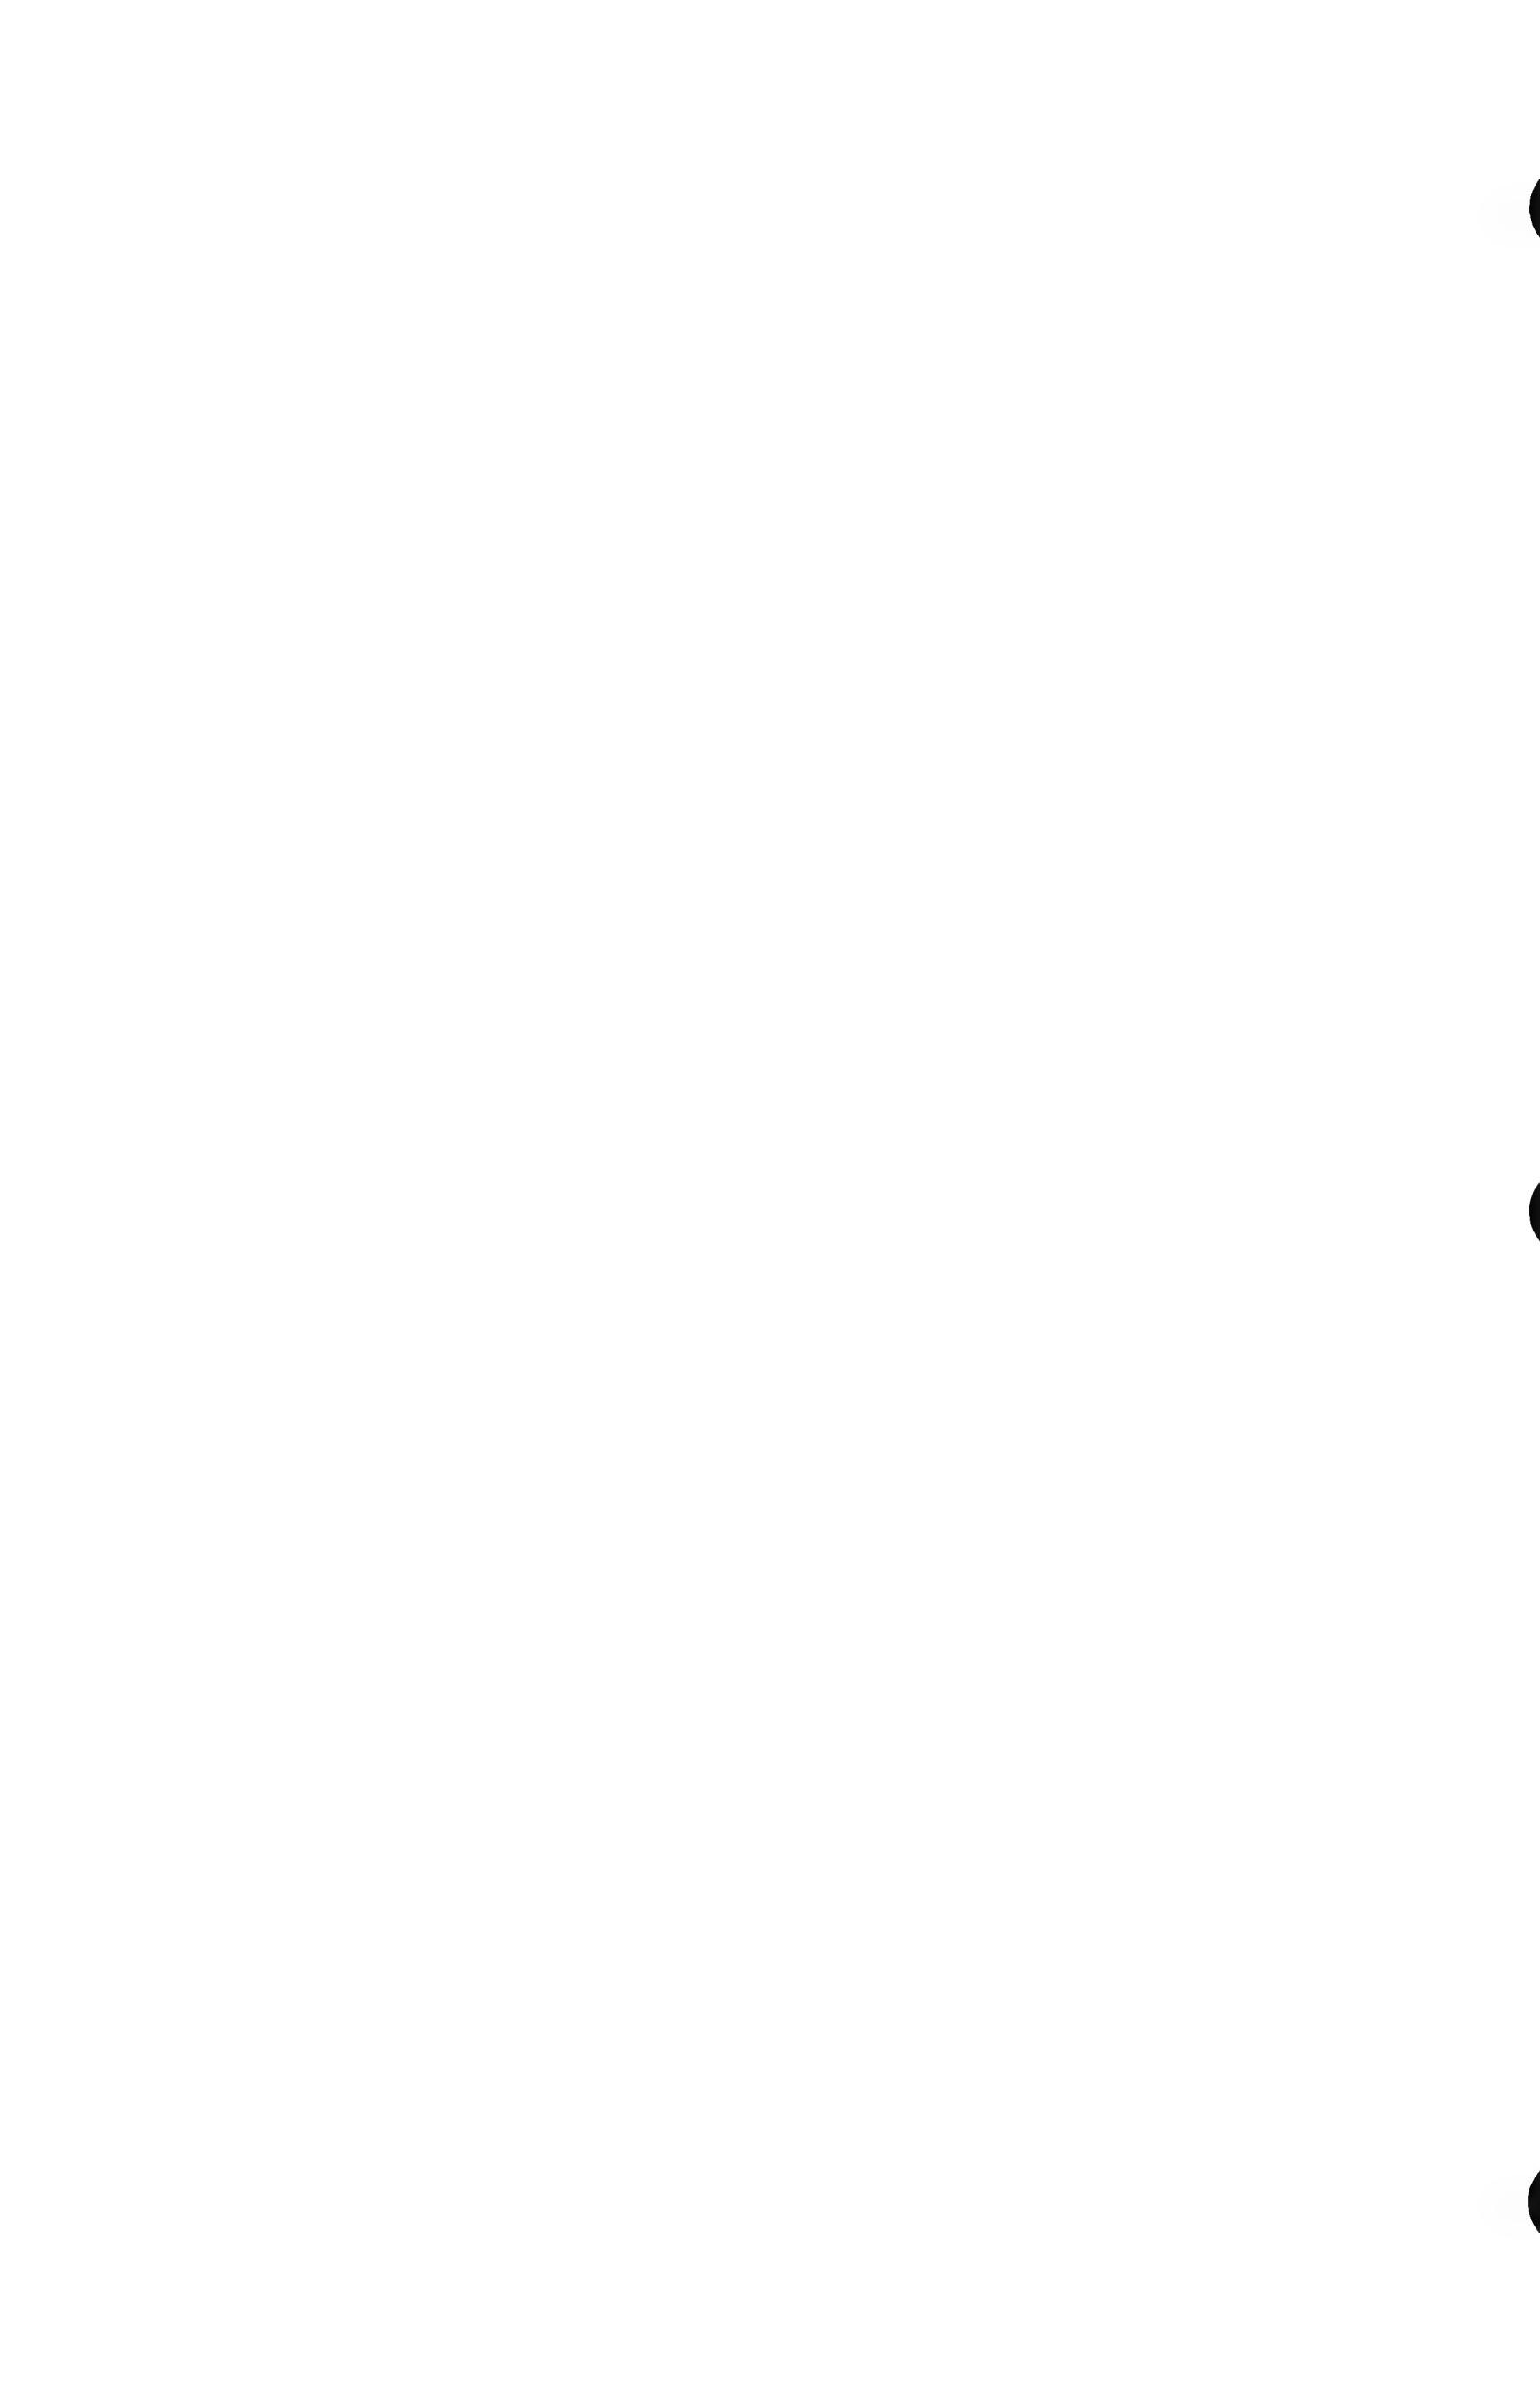

14 July Rained most of the day, so worked in lab. at 1600 hr went to 530 CES and found Lachesis muta under the Daraea fern. Set up Dan's remote photography stuff, only to find that for some reason it wouldn't fire. Started raining at ≈ 1800 hr. At 1837 hr the Lachesis head appeared (by now it was virtually dark), and for $23\frac{5}{6}$ min 56 sec it crawled out into the area where it hunts, then back into the Daraea, then into the forest \approx SE of its site. While crawling it frequently tongue-flicked, pointed its snout at the ground, and turn the head side to side. At least twice it lifted its head up a few cm to inspect low palm leaves. Thinking it would disappear, we caught it. When Dave and Dan went back for the can they caught an Oxyrhopus petola on the trail (≈ 1930 hr, CES) — said its only response to them was rapid crawling. As for the Lachesis, hopefully we had the good fortune to see this snake initiate a site change. An alternative possibility is

Greene, H.
1987

14 July (continued) that our presence caused it to move, but I think that unlikely because of its behavior (apparent searching, not flight) and the fact I've had no evidence of such effects w/this Lachesis or others in the past. I also wondered if it was bothered by the rain (water had pooled under the Danaea), but it has rained many times in the past w/out this or other Lachesis moving.

15 July Spent the morning preparing a receiver and transmitter - ch 3, 27.575 (frequency). Temp. calibration (beats/100 sec) 26.4°C, 92; 30.4°C, 111; 32.8°C, 124; 33.6°C, 134; 37.0°C, 154. Processed the snake right after lunch: SV 1370 mm, tail 144 mm, 1.8 kg. Snake never got especially riled up, but while we were measuring it protruded and retracted one hemipenis. Just as we finished it spontaneously evacuated a large fecal and uric acid mass, both very wet. Spines of Proechimys (or less likely Heteromys) are clearly evident. Less than an hour later, we released it on the Danaea fern, and its responses to gentle prodding w/ snake stick were to crawl or to cover its head w/ a coil and elevate and gently sinusoidally wave the tail, while periodically (≥ 3 times) extruding and retracting the hemipenes. Then we walked out to Sendero

Greene, J.
1987

15 July (continued) Sabalo - Esquina but could not locate the ♀ Bolitoglossa asper that was on the treefall day before yesterday. (Today was the first day w/ lots of sun in a long time, so I expected to see her). On the way out, on Sendero Oriental, we saw a troop of Ateles, and on the way back a troop (same) and not far away a lone ♂ Alouatta. At x 1630 hr Beth Nowell pointed out a small brownish slender snake crawling off the trail, so I slapped a hand down as its head went under a leaf - then released it was a very small B. asper ad let go fast. Pinched it at midbody 2-3 times and it never struck - uncharacteristic for small Sericopholis, and I learned a lesson. In the evening heard a talk by a group of Cuna Indians from Panamá.

16 July Left x0820 hr w/ Dave and Dan. First checked at ccc 700 and found the big Lachesis muta well under the SE(?) side of the fall tree, head not visible. Walked to \approx 100 m before the end of the SSO to look for an adult Lachesis muta that Julie Denslow saw yesterday - we found her flags but not the snake. Then walked in by way of the LOC & CES, got the receiver, and went back to search for the ♂ L. muta at CES 530. Soon found it at \approx 15 m N of previous site,

Greene, H.
1987

16 July (continued) curled up against the overhanging edge of an old fallen tree and very near a stilt palm as well as several Welfia. I touched it lightly and it flinched, so seems OK. Partly cloudy and sunny until ≈ 1000 hr, then intermittent rain into the PM. After dinner Dave, Jan, Feyrer Godíras (just arrived from Santa Cruz) and I went out to CCC 700 to check the Lachesis muta, then back and out the SOR to the concrete bridge. Much of the time a light rain was falling. Walking in and out the CCC, we saw at least 5 Potos flavus in canopy trees - our attention was drawn to them by crashing sounds (branches breaking?) and we got good views of them locomoting. Twice they were in pairs. The bushmaster was not under the fallen tree, and we spent ≈ 15 minutes in the vicinity w/out finding it. Periodically I wondered, especially when bending to peer at some spot and thus unable to watch around me, what it would feel like to be bitten by surprise by that big snake! On the way back on CCC (≈ 400 ?) Feyrer spotted a small adult Dasyurus novemcinctus under the boardwalk, frozen at our approach but w/ its tail exposed. He managed to catch it, and we observed an open, maggot infested hole (jagged, $\leq 20-25$ mm \varnothing)

Greene, H.
1987

16 July
(continued) at the base of its tail - we surmised only could have been made by a lion or jaguar, and that this armadillo will die from the wound. A complicating factor vis-a-vis surviving a predator encounter!

17 July At \approx 0830 hr checked at 700 CCC again w/out finding the Lachesis muta. Then went to 530 CES and found the ♂ a few m S of yesterday, under the stilt palm that grows around the end of the log. Took polaroids w/ Feyrer's camera. Went to San Jose for the weekend.

20 July Back at La Selva by 1030 hr. Learned that Rocío López had found a small adult Lachesis muta at \approx 1700 LOC. She was stepping up onto a log, slipped backward on some withered palm fronds, and bump the snake, which drew back. That was on the 17th. Dave and Dan photographed that snake on the 18th, and people from the GAPS project saw it again on the 19th. Dave and Dan also checked the Lachesis muta at 530 CES, and found it during the day on 17, 18, and 19 and during the night on the 17th & 18th. Bruce Means and his two sons arrived this afternoon for a brief visit, so I showed them that snake at \approx 1600 hr. During all day sightings the snake was head down and "sleeping", whereas the two nights its head was "up"

Greene, H.
1987

20 July
(continued)

but snake was in the same position. After dinner (1930 hr) Feyner Godivas led several of us through the Ecological Reserve swamp and around the Camino Circular. We saw only two Dasyurus novemcinctus and a few Eleutherodactylus on the loop, but there were a fair number of frogs in the swamp: Hyla leucophaea, H. leachii, a big ♀ Smilisca baudinii, several Agalychnis saltator, and Gastrophryne pictiventris calling. At \approx 2200 m I spied an adult Ingerophrynus inornatus \approx 3 m above the boardwalk in a small tree, got it down, and palpated out in order of regency an adult H. elaeochroa, and two adult A. saltator. State of digestion varied from none to only pelvis and hind feet, suggesting that they were eaten at least hours apart—and that such a meal (1 such frog) does not result in a cessation of foraging. Feyner spotted a mammal high in a tree on the N edge of the swamp, and we got a good view of it through binoculars: Caluromys derbianus.

21 July Left at \approx 0815 hr w/ Dave, Juan, Bruce and his sons.

We walked across the Sendero Cantarana and out the loop, where Dave checked briefly at C15 700 for the adult Hachisus muta we watched there a few days ago. Began raining soon after we started up the Southwest Trail. At 550 700, after the 3 Meands had passed by, I spotted a yearling

Greene, H.
1987

21 July (continued) Bothrops asper crawling rapidly off the trail. Turned sideways and bit when pinned w/ my foot. Next we turned south on the LOC and checked the Lachesis muta first spotted by Rocío López on the 17th. Found it coiled and "asleep" at the same site, fully exposed, but difficult to see on leaf litter. ^{(I'd guess this snake at ≈ 1.6 m).} The snake is < 1 m W of a large ($5-1$ m \varnothing) old fallen log. Once when I was leaning over the log it flinched once, but otherwise we didn't disturb the snake. Walked in on the LOC and CES, and ≈ 1015 hr found the L. muta missing at CES S30. Bruce, Dave and I picked up a receiver and went right out and soon picked up a weak signal, but couldn't get it focused into a sharp beep at first because of interference. As I was slowly walking and searching I stepped inadvertently on a < 1 m "Philodendron" and as the plant bent over saw a "large yellow snake" - adult Lachesis muta! - drawing back from my right heel. This new snake is ≥ 2 m and very fresh looking and yellow; coiled fully exposed between the Philodendron and a young palm and only a short distance in several directions from old fallen logs. Next located the 1.5 m L. muta δ w/ the radio, under an abandoned boardwalk plank ≈ 10 m from the large new snake; only edge of a coil

Greene, H.
1987

21 July exposed. I am still concerned that something is wrong w/ that snake. The larger snake maintained a head-up alert posture for the next 30 minutes or so of photography, but when I returned \approx 1400 hr w/ 4 people for more photographs it was "asleep" and never moved while we were around. Rain ceased in midafternoon, but stayed overcast and cool. By 1900 hr there was much clear sky and stars.

[Forgot to note that on the afternoon of 16 July Mauricio Quesada caught a Leptophis depressirostris in the lab clearing that had its left 20th subcaudal obviously clipped. The snake was an adult and photographed by Dave and Ian, but I didn't get measurements before it was released.] At 2100 hr checked the two Lachesis muta at 550 CES. The smaller ♂ was still under the discarded piece of boardwalk plank, but alert. The larger snake had moved \approx 1 m NW (?), out from under its plants to face a large "tip up" of an old fallen log. That snake was in an alert posture, w/ head up over the coil and facing the tip-up. Within seconds of us approaching and shining a light on it, the snake oriented its head to us. Some further thoughts on the initial encounter w/ this snake: I marvel at the way perception of certain aspects of the situation were coupled w/ instant action on my part, prior to full cognition of "it's a bushmaster, etc."!

Greene, H.

1987

21 July (continued) When I jumped back I ran into Bruce Means, a big guy, who said I was emanating a cloud of adrenaline that affected him before he fully knew what was happening! Dave says the next thing I did, inexplicably, was to collapse the antenna on the radio I was carrying. The snake was drawing its head back into an S-coil when I saw it, but based on the two previous ones I've seen, ^{strike} I don't think this one was about ~~four~~ ^{so} - there was more of the exaggerated S-coil or flattened neck seen prior to striking in the others. However, we were all clearly impressed, and tonight Dave remarked about the danger aspect of all this - he has been pondering the 80% mortality rate for 5-6 treated (w/ serum) cases.

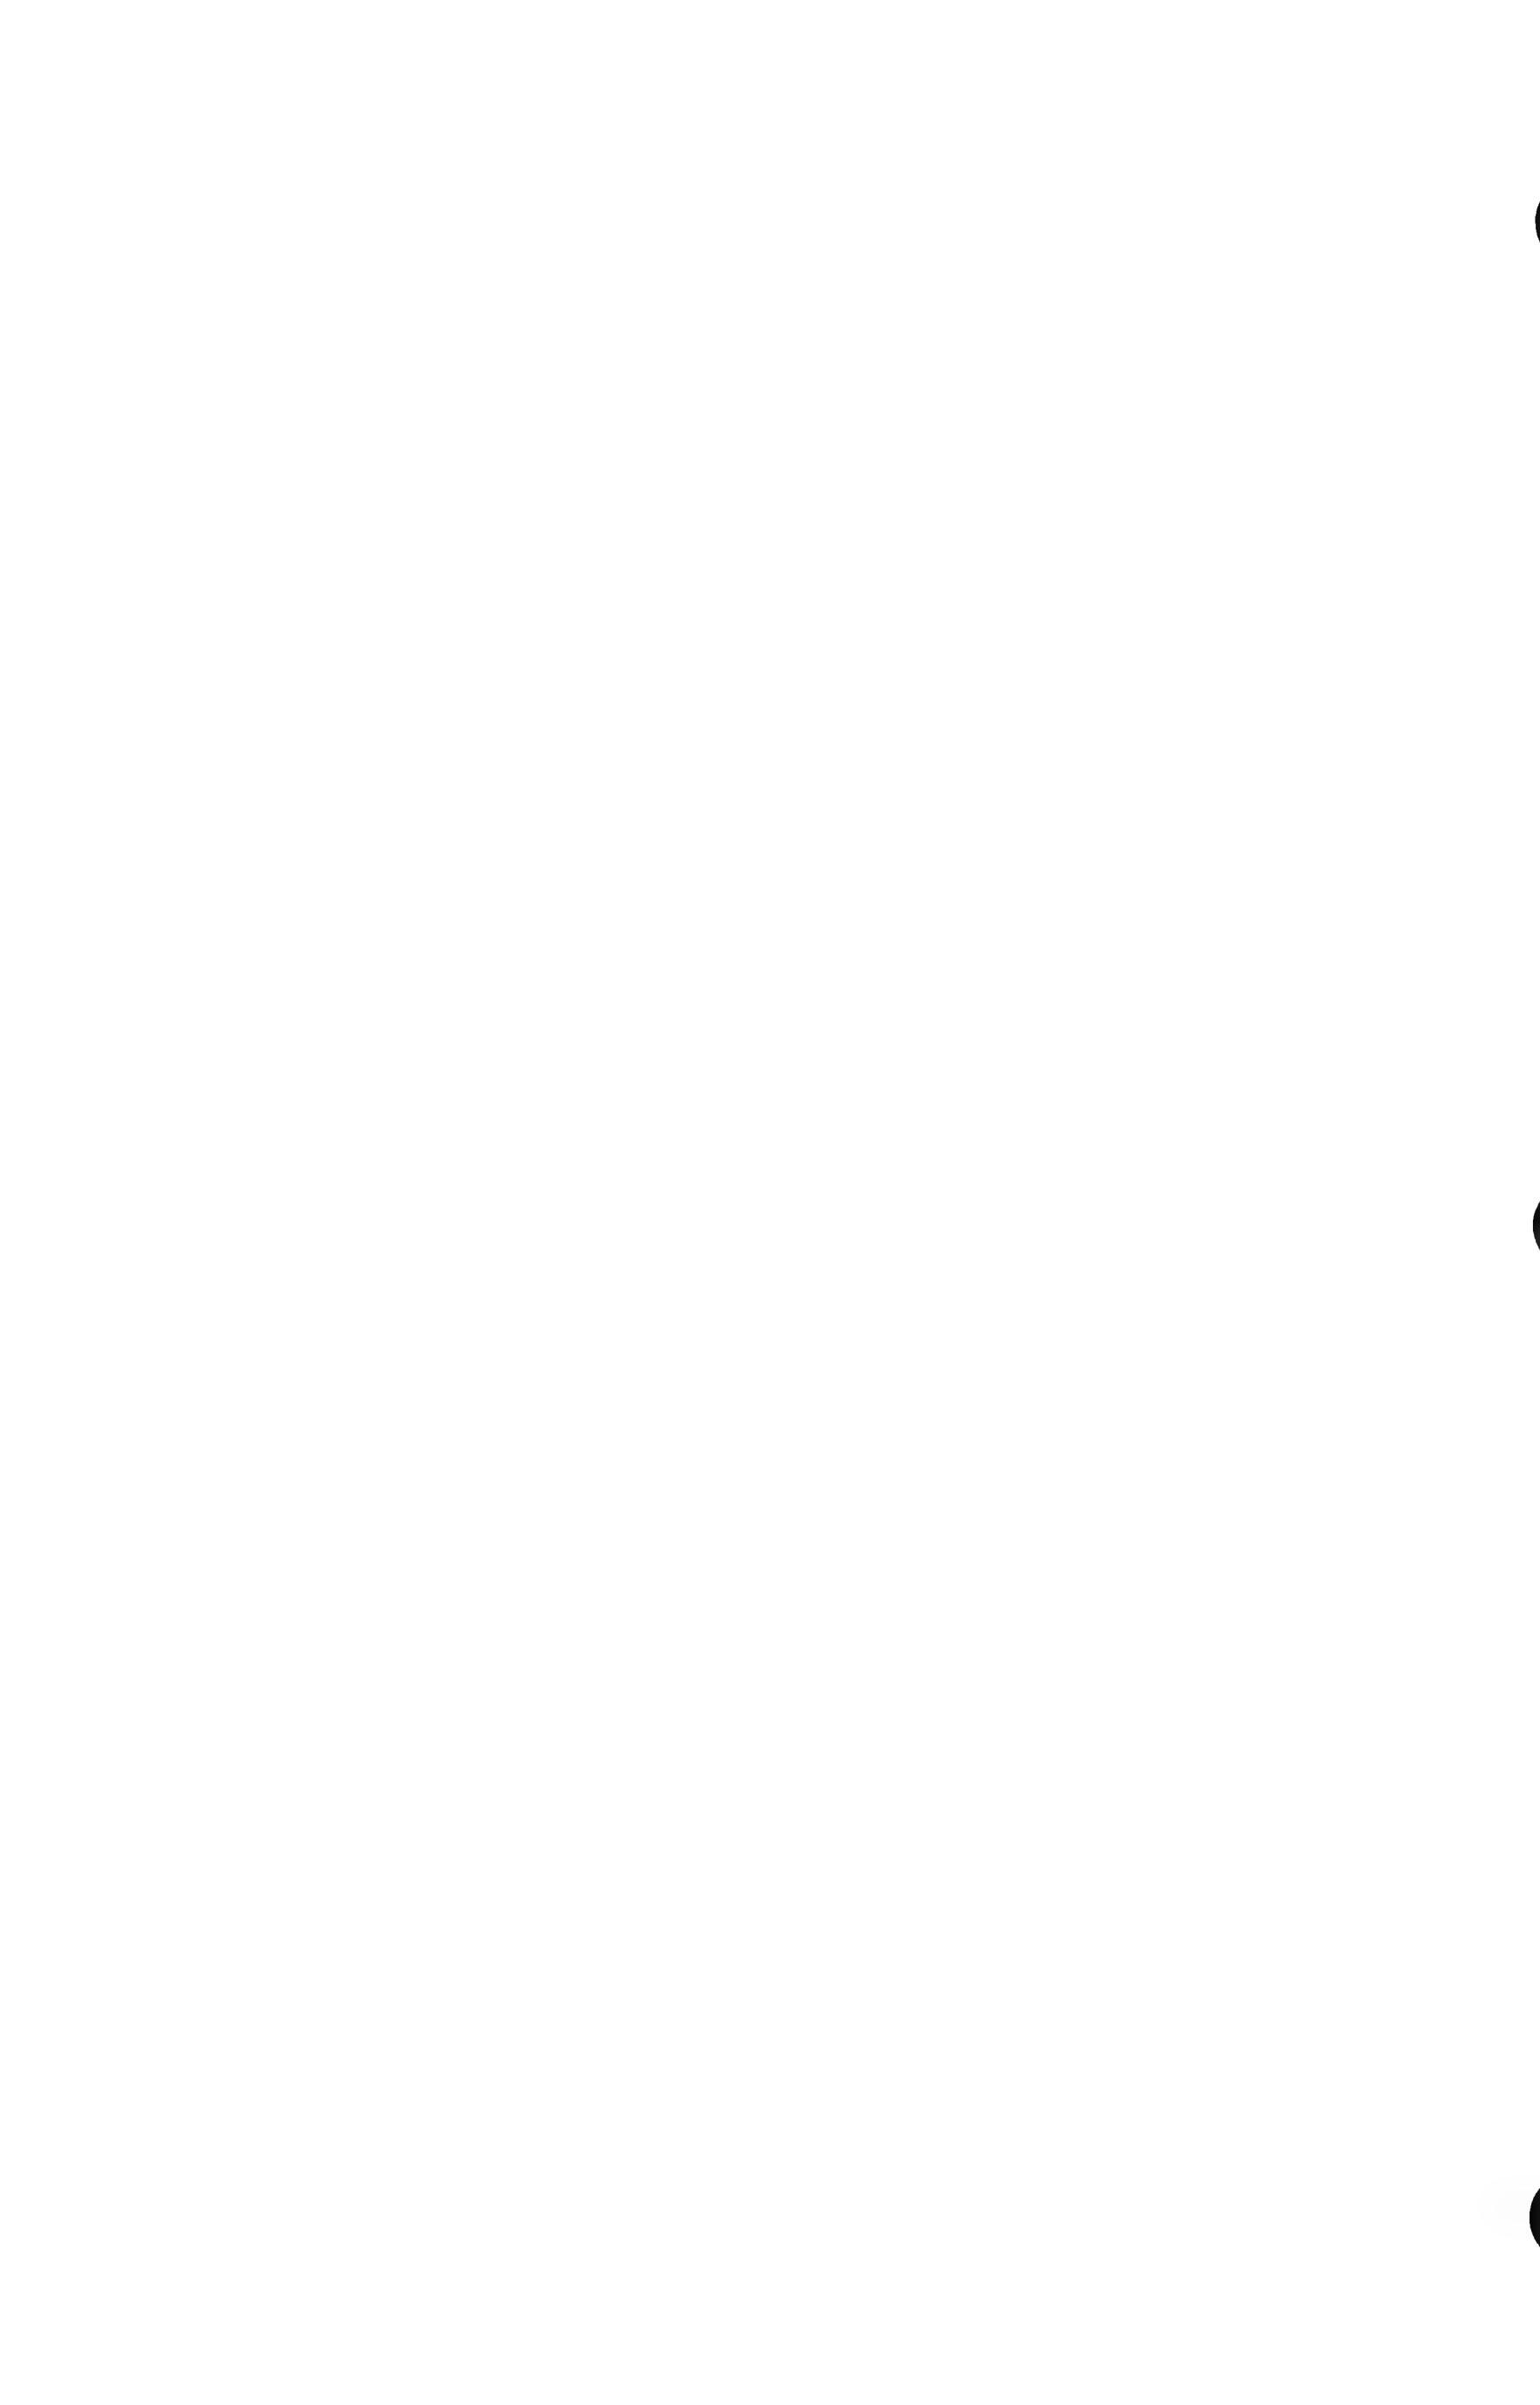

22 July Went at 0800 w/ Dave to check the two Iachesis muta at CES 550. The smaller ♂ is in place under the boardwalk, "asleep." The big one was gone, and \approx 15 minutes of searching failed to turn it up. Before and after lunch I photographed a large ♂ Iguana iguana resting on dense "shrub" tops next to the river bridge - probably the same individual I often see sleeping high in a small Cecropia tree nearby. Mostly sunny today, punctuated by a brief shower \approx 1230h. A visitor saw a long, slender emerald green snake in the Reserve Swamps that sounded like a Leptophis ahaetulla from his

Greene, H.
1987

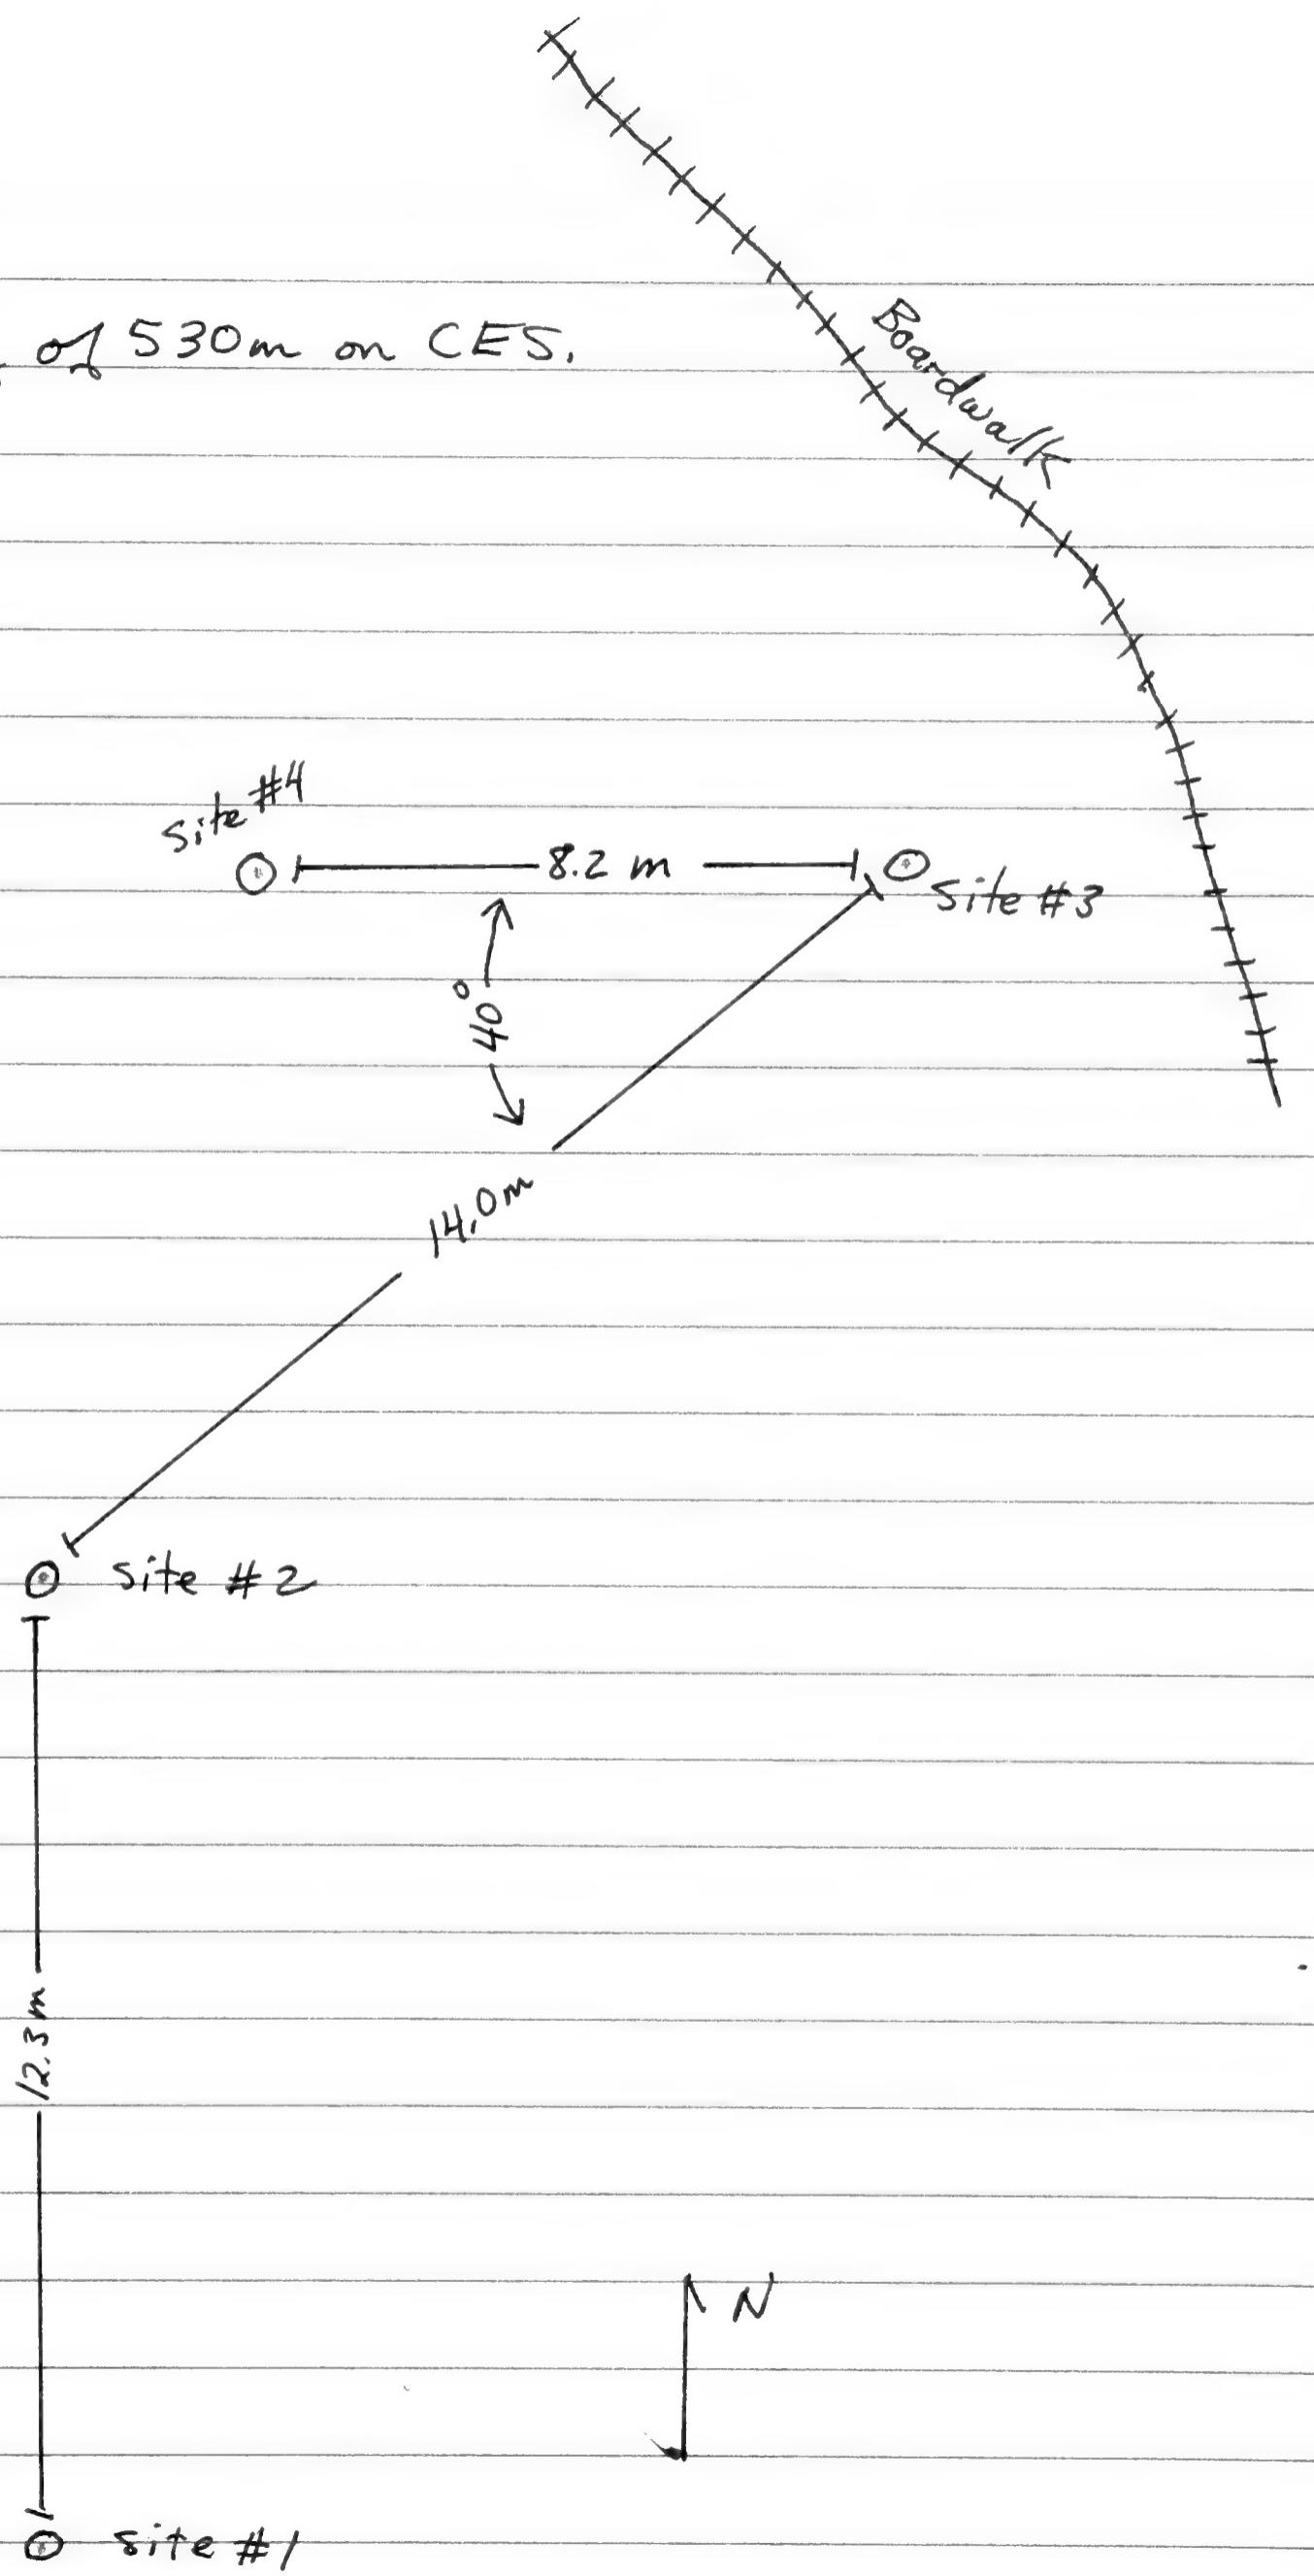

22 July (continued) description. He was first attracted to a large brown frog (& presume Smilisca baudinii) that was hopping on the emergent aroids, then saw the snake coming and peering after it. This morning Dave Hardy hiked out to LOC 1700 and found the Hachisus muta there ("Rocio") in place and asleep.

23 July Hard rain at dawn, tapering off (for the moment?) by 0800. Eric Weiner just told me that about a month ago he saw a Cicaba nigrolineata take what was almost certainly a bat near Cabina #3. He heard a commotion at the forest edge, and saw the owl on a branch from \approx 10 feet. It was eating the object, which from appearance (including apparent wings) was a bat. He saw 4-5 bats fluttering around the owl, and thought they were either catching mosquitoes or harassing the bird (he saw it flinch once or twice when they flew close). Before lunch Dave Hardy caught a Leptophis ahaetulla gliding off the CES at 225m. It is a gravid ♀, 856 + 525 mm, 107g. Palped from it an Agalychnis saltator, swallowed headfirst, 2.5g, SVL 49 mm. From \approx 1415-1500 Dave and I mapped out the sites for Hachisus muta at 530-550 CES (map next page). Site #1 is where the ♂ ("Juan Antonio") was first found under ferns and a small tree. Site #2 is where it next moved against an old log and

Greene, H.
1987

23 July
(continued) Vicinity of 530m on CES.

Greene, H.
1987

23 July
(continued)

under a stilt palm. Site #3 is its third resting place, under a piece of discarded boardwalk. Site #4 is where the large adult ("Hariito") was, between two plants (a small palm and a "Philodendron") 80 cm apart and 60cm high. It's hunting site is 1m W, and \approx 0.5m from (and E of) a 1.1m high tip-up of an old log.

24 July

At \approx 0830 hr checked the ♂ Lachesis muta at 550 CES and found it in place and inactive under the plank. Walked back through the station and out SOR to the steps to Rafael's House, where Phil Debries saw a <1m Bothrops asper yesterday. The snake had been coiled on leaves on a log, partially hidden under leaves, but was gone this AM. Picked up a \approx weak old cat scat on a faint trail leading downstream from the house clearing. When I returned to the lab Orlando presented me with a big ♀ Polychirus guttatus that he found this morning on a tree beside the river bridge. It has palpable eggs, and gapes and orient when prodded gently.

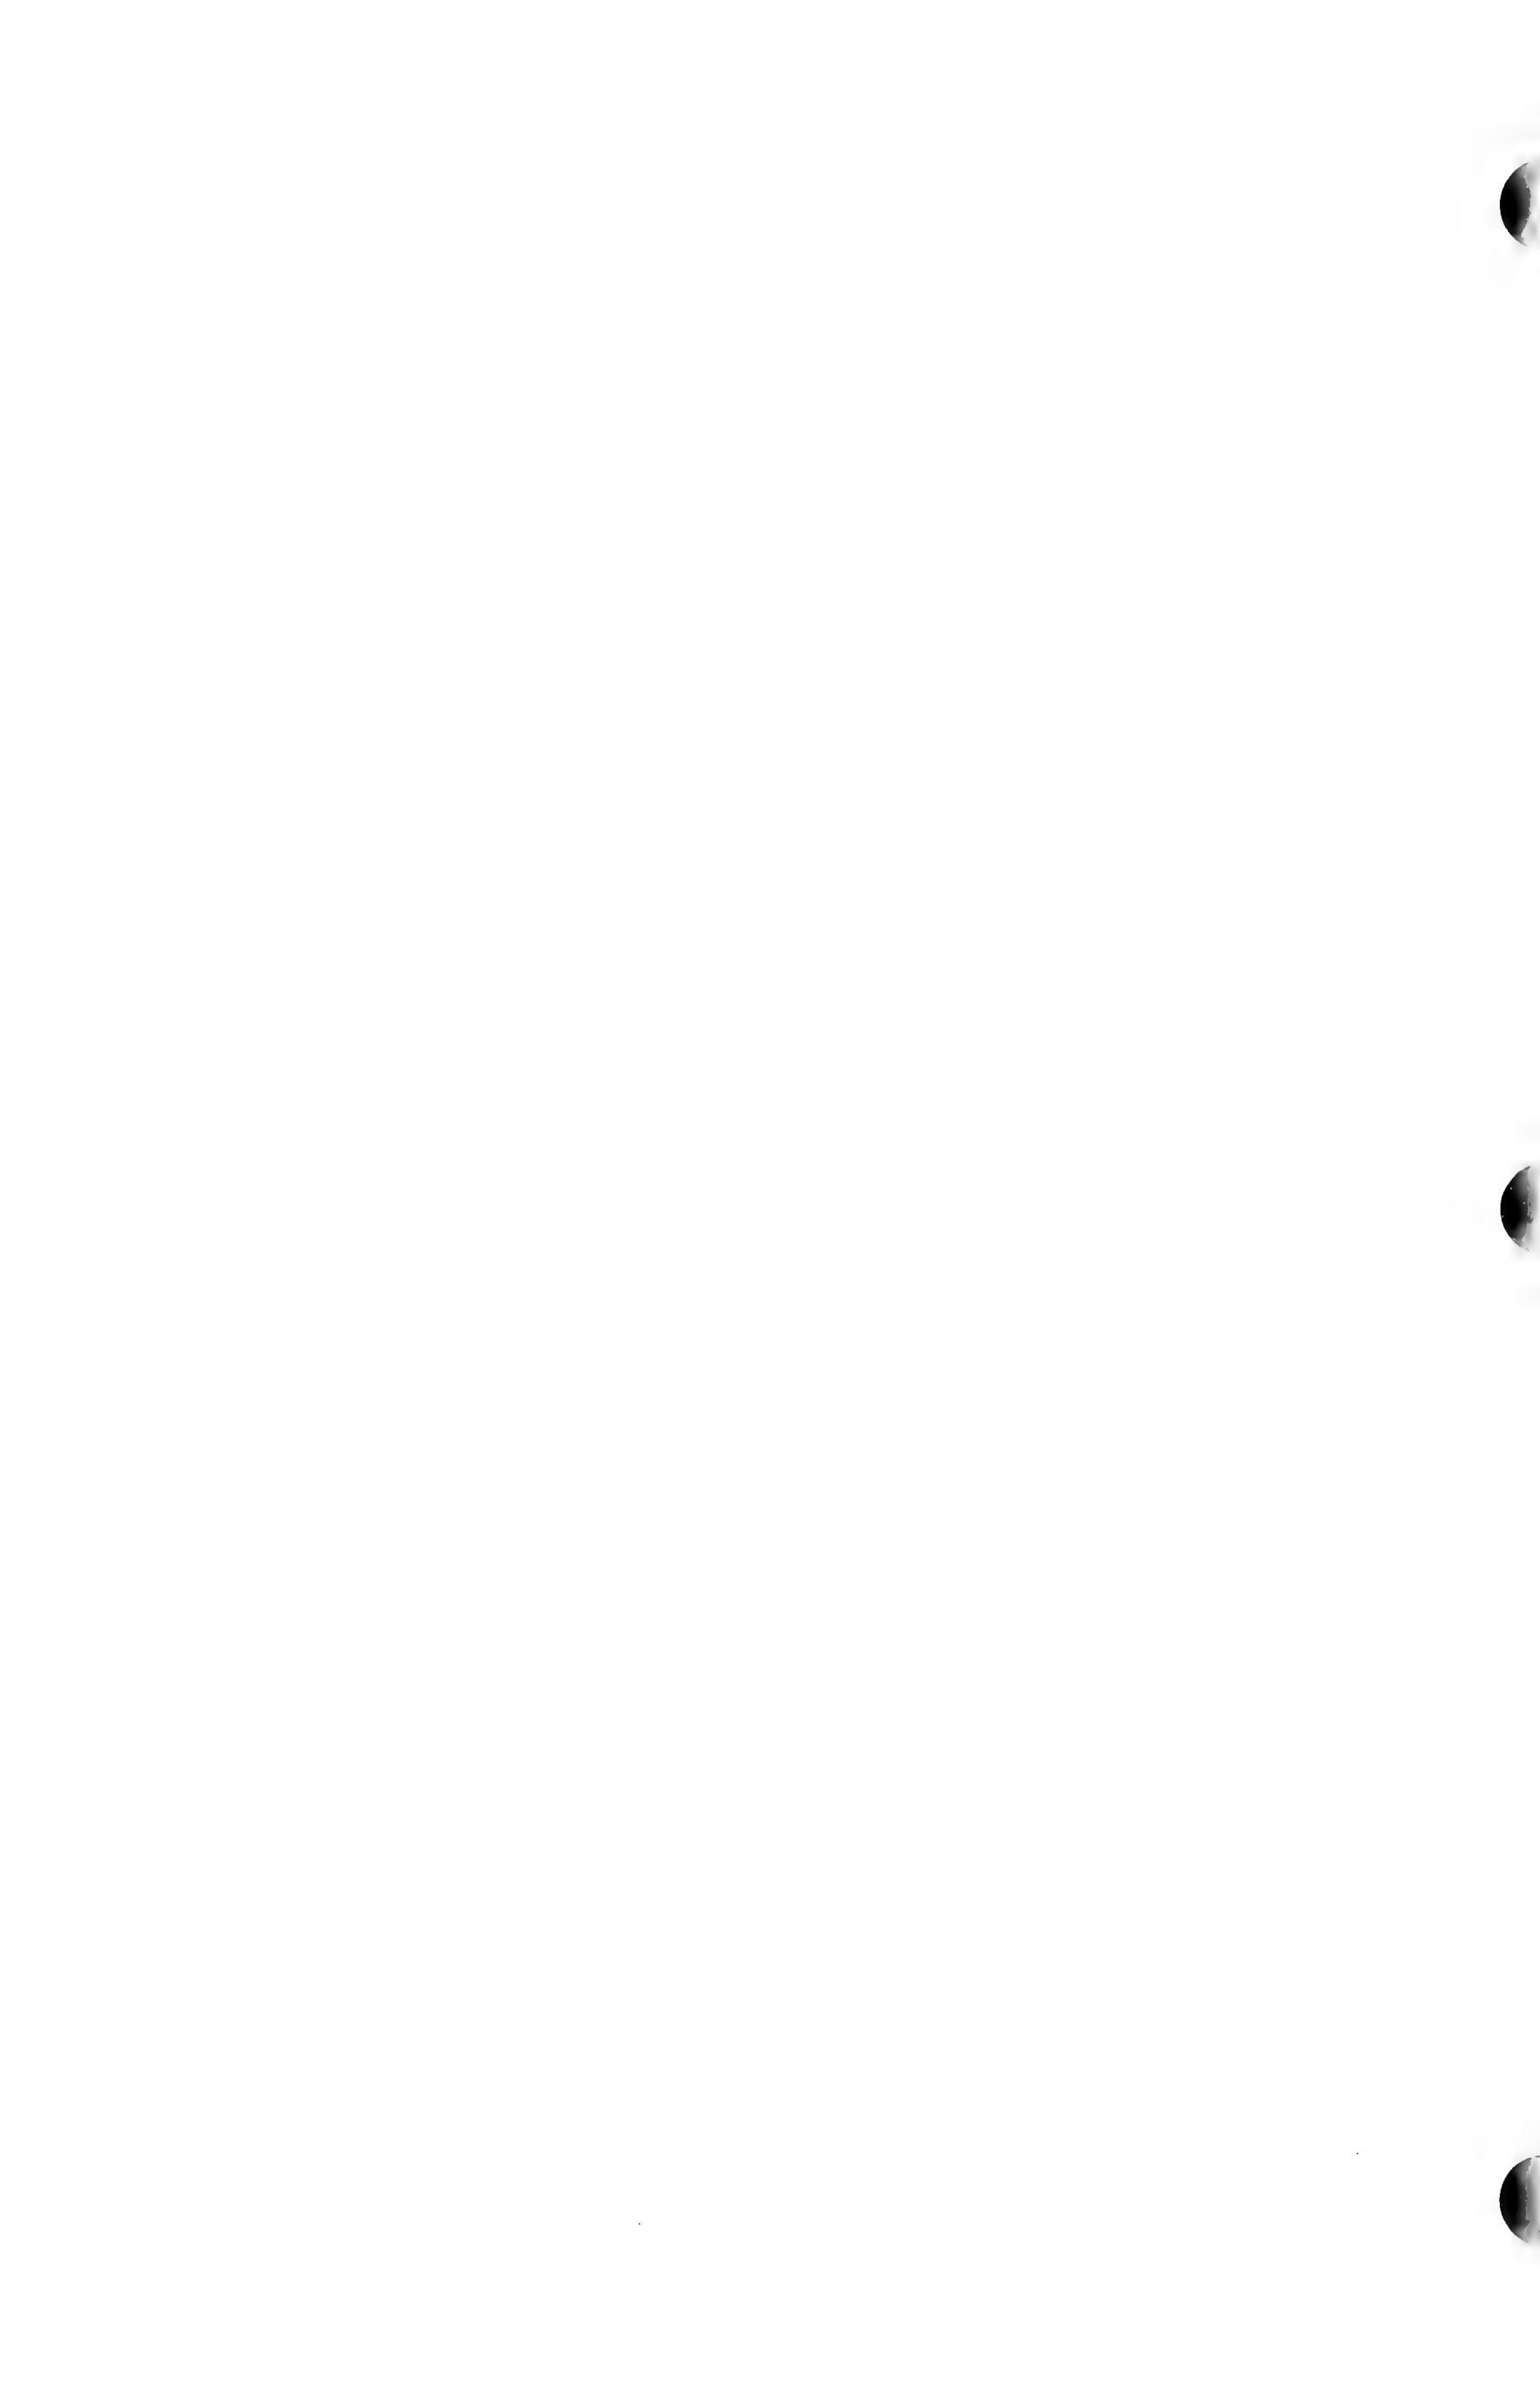

25 July

Partly cloudy and sunny this morning, rain off and on all afternoon. From \approx 9-11 walked around taking photos for Carmen Rojas, including out to 200 Holdridge and to the Susa Bridge on the CCL. Saw no snakes. At noon Lou Higgins brought me a large and a small cat scat, and Orlando Vargas brought a large one yesterday - clearly there

Greene, H.
1987

25 July (continued) a Felis concolor and/or a Panthera onca in the area recently. Forgot to note that last night \approx 2030 hr there was a large, yellowish Tamandua crossing the bridge from south to north. at 1910 hr, walking back to Cabina #1 from dinner, I found a yearling Bothrios asper crossing the concrete - bit my boot two of the three times that I restrained it. Walked out to and around the Arboretum from \approx 1930 - 2130 hr. at 1956 hr found a Nothopsis rugosus in leaf litter near a Termite swarm, in a pile of branches next to the boardwalk (on the Sendero Sur, before the Arboretum). It was immobile w/only a few cm of tail and hindbody exposed when Nancy Gieg saw it, and the only response to handling was periodic thrashing alternating w/ rigidity of parts of the body. also along the boardwalk heard branches cracking overhead, and got a good view of a Bassaryium semimaculatum - gray coat, tail not thickly woolly and held well off the limb, and rapid jumping locomotion. On foliage in the Arboretum, saw Agalychnis Saltator (2 m high, on palm leaf), Eleutherod. fitzingerii (1 m, on leaf), and E. diastema (calling from under a vine leaf on a tree trunk). at \approx 2100 hr I spotted a Hoplophis degressivostis asleep \approx 4 m up a sapling, coiled on foliage above the stream. Only response to

Greene, H.
1987

- 25 July (continued) handling in the dark was throating and copious cloacal gland secretion, although later indoors it readily gaped and struck. After we parted, Jan and David found an adult ♂ Micruroides alleeni crawling under the boardwalk on Sendero Cartanaro, just before it hits the water, at ≈ 2200 hr.
- 26 July Photographed animals this morning. The Polychrus gutturosus could switch brown to green w/in seconds, jumped w/out hesitation to the ground from a height of $> 1\text{ m}$, and could move fairly rapidly at times. I never saw it curl the tail round a branch, but there was certainly contact along its length. Interestingly, when the animal switched to green the tail remained reddish-brown. It repeatedly gaped and extended the dewlap when threatened w/ a finger. Phil DeVries told me the plant it was on is Helioscapus (Tiliaceae). SVL 70, tail 550 mm, 77g. The claws are exceptionally sharp! The Micruroides alleeni consistently tried to crawl away rapidly w/ broad curves, but repeatedly exhibited a suite of responses when restrained. If it halted because someone appeared in front, the animal froze w/ head jerked back in a tight, flat S-coil. This appeared to be "tail mimicry" rather than preparatory to striking. If restrained, the body was flattened; the tail was curled slightly and waved, though not especially elevated; and

Greene, H.
1987

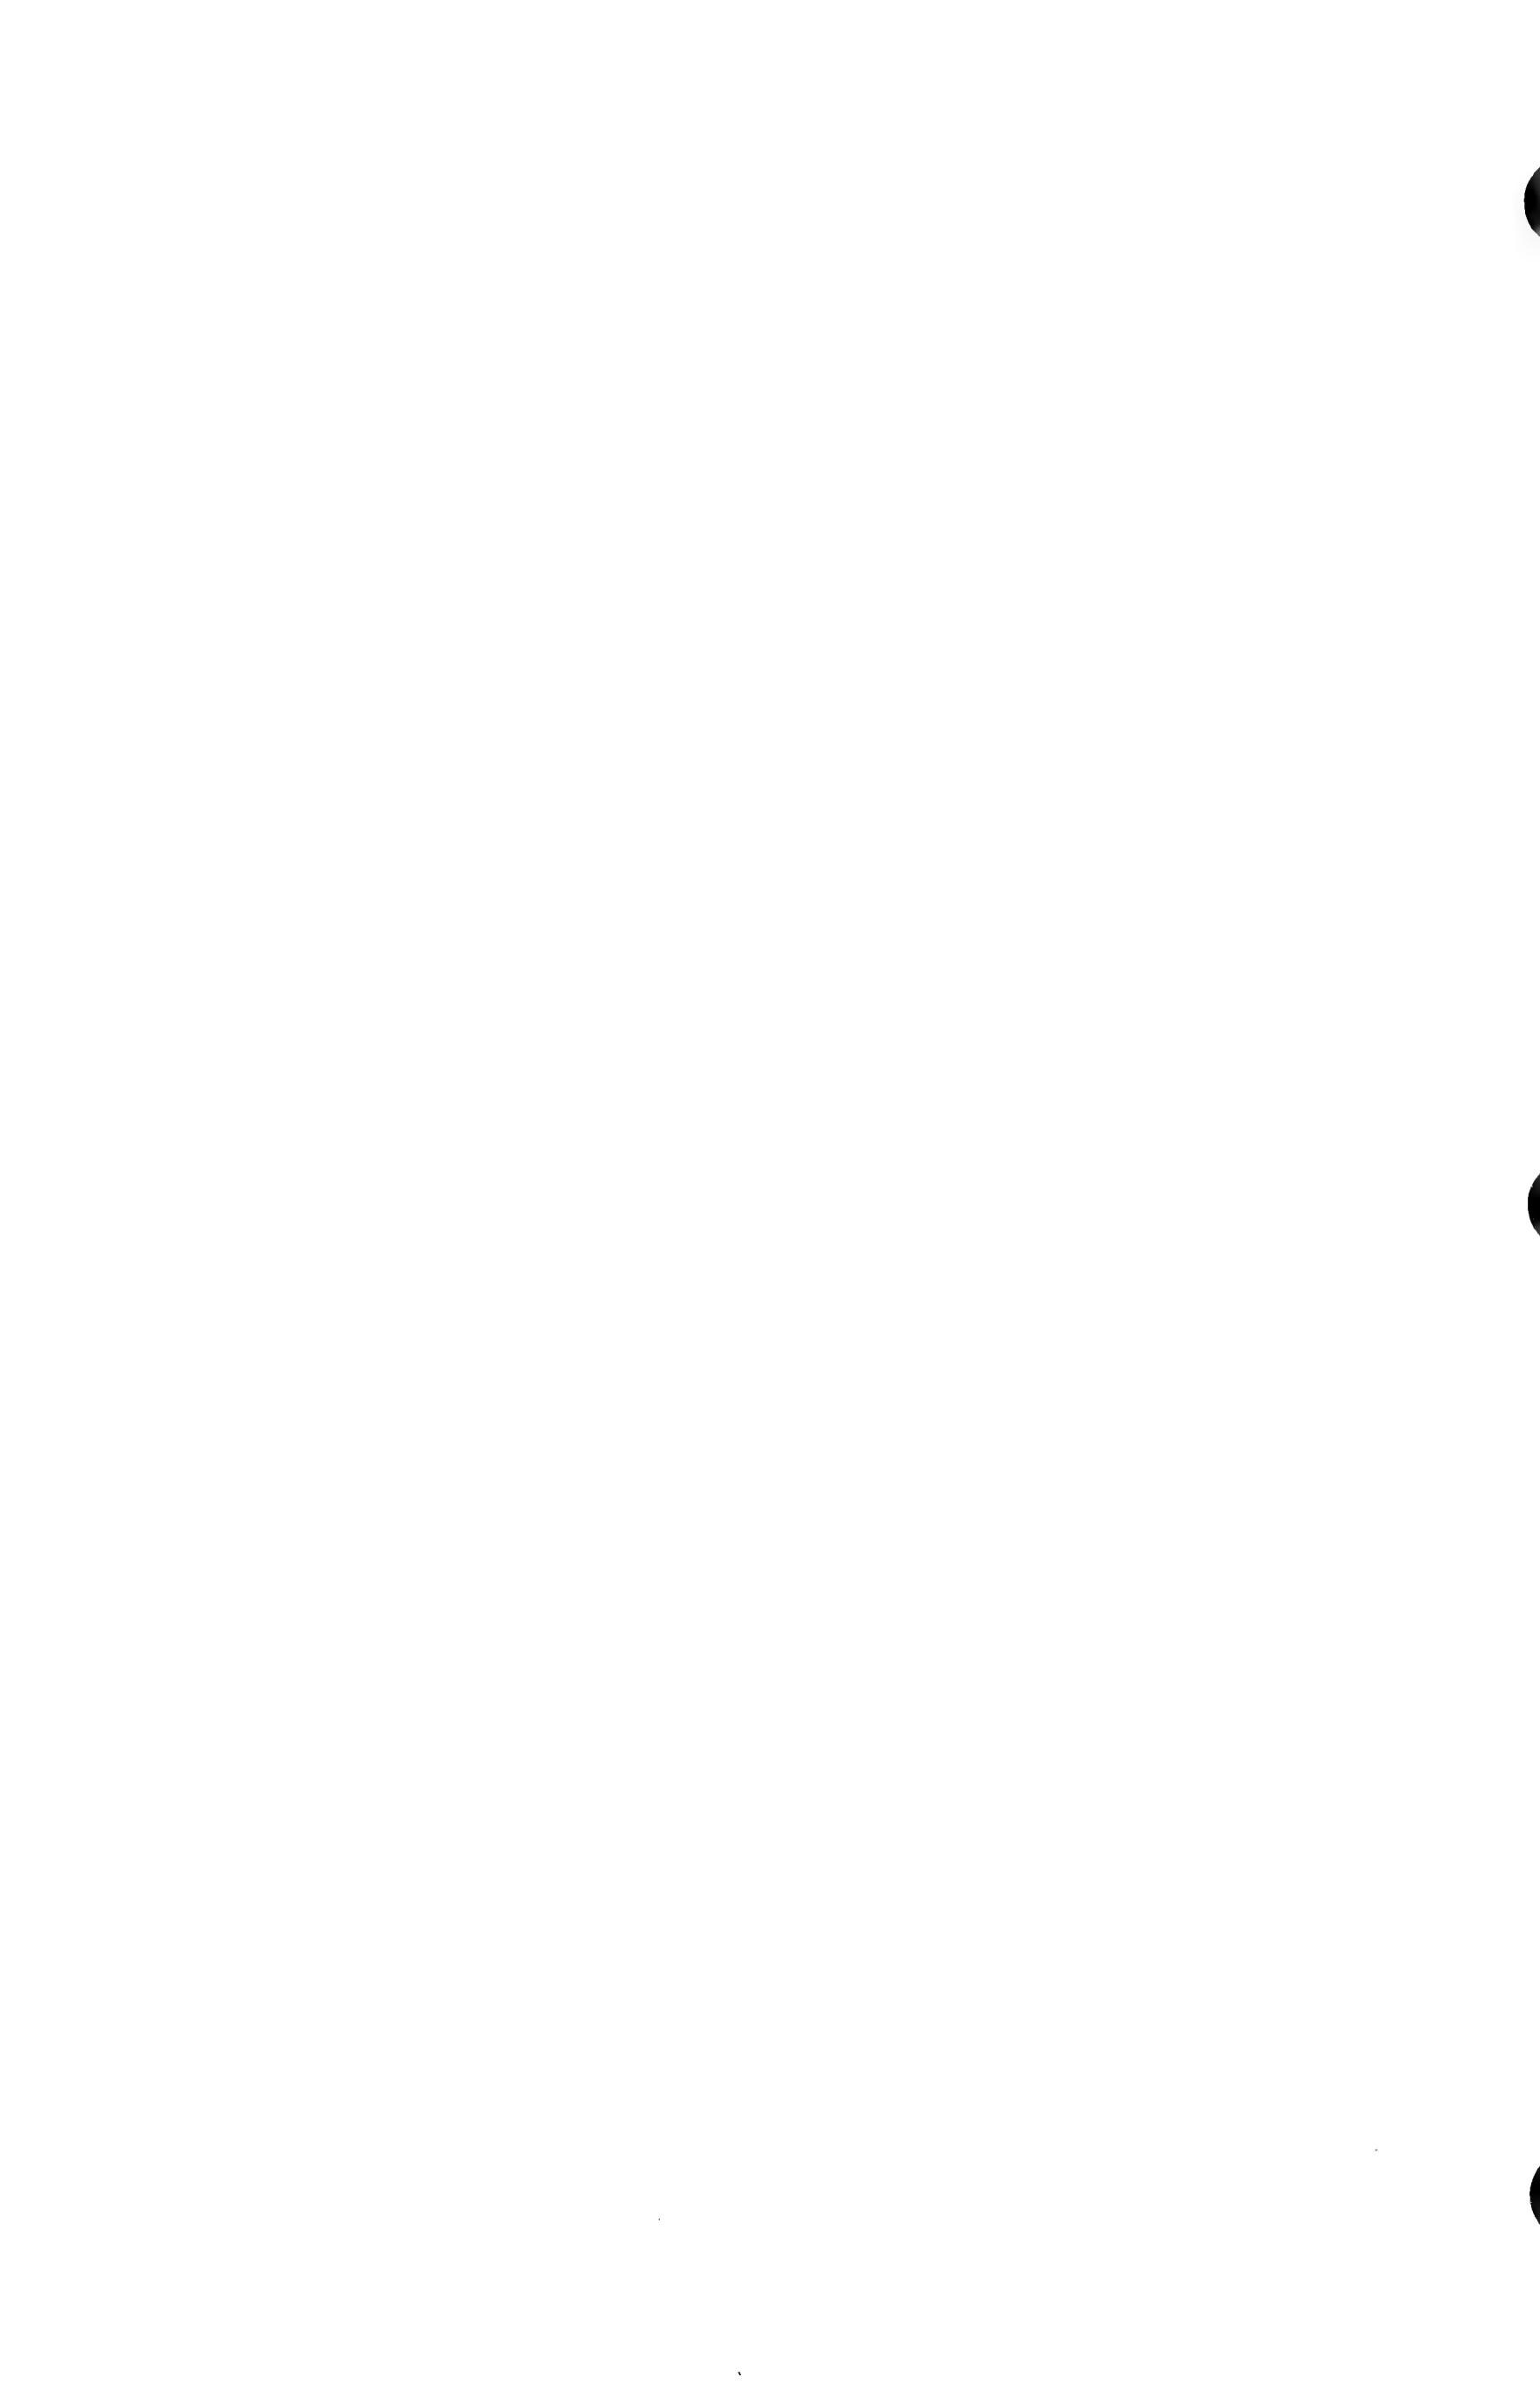

26 July (continued) the head swinging back and forth - at least twice I saw it bite and briefly hold on to the plastic box w/ which I restrained it. I did not experience flicker fusion of the bright bands, but I repeatedly found it impossible to distinguish head and tail when the snake was moving rapidly.

at \approx 2030 hr Dave Hardy found an adult ♀ Bothrops asper coiled w/ head hanging out over the outer body loop, facing the boardwalk and completely out on the cleared trail at CFS 200. He took photos, then returned for several of us, and when we approached the snake glided into the forest edge. It crawled around a buttressed tree, several times turning to face us w/ an S-coil - and once this was from under a large hanging palm leaf such that a pursuer would have been ambushed. Movements were frequently jerky, and involved sudden, sliding changes of position and direction.

27 July Left after lunch for San José.

28 July Presented seminar (in Spanish) at the Instituto Clodomiro Picado.

29 July Monteverde, Provincia de Puntarenas, Costa Rica arrived here \approx 1600 hr and got a room in the Pension Quetzal, run by Bob Lewis. Carmen Rojas and I rented a Toyota Land cruiser from the OTS for \$200 for the ride, and we needed the

Greene, H.
1987

29 July (continued) rough suspension for the stretch from the coastal main highway up to here - a very rough road, with some fine views of the Golfo de Nicoya. Saw several Gekkosaura similis basking on trees on the way up. Visited Patricia and Michael Fogden briefly before dinner.

30 July after a leisurely wake-up and breakfast, we went to the cloud forest preserve. Along the road I saw several adult Sceloporus malachiticus basking on old dead fallen trees. We walked from ~1030-1430h, except for a break for lunch at "the windows" - where there was a spectacular set of views to the Atlantic and Pacific slopes. We couldn't see the coasts because of clouds. Weather alternated overcast, thick fog, and sun, but never really rained on us. Only herps I saw were two Anolis species. Shaggy moss, ferns, epiphytes of all types, and liverwort everywhere. Several streams and waterfalls, and even one spring. Overall impression was of more dark green stuff than at lower elevations, and of less exposed bark - there is a virtually continuous, soggy, living layer in this forest. After returning, I photographed an adult Bothrops lateralis that Bob Lewis found on his motorcycle seat next to the pension yesterday.

31 July After breakfast we went down the road

Greene, H.
1987

31 July past the Pension Flor-Mar, hoping to see a quetzal.
(continued) On either side are cleared pastures w/numerous tho widely spaced in places large forest trees.
Overcast. Tried to locate a singing bellbird without success. Finally in quick succession Casmen spotted a ♂ Procnias tricarunculata calling from the crown of a large tree — and we had a fine view out to him because of the road's slope — and I located a ♀ Phasianotrichus mocino in another tree.
a fine walk, after which we visit the Fogdons. Left Monteverde after lunch at the Pension Quetzal, and had a great ride through pouring rain down the hills. It took us six hours to get back to San José because twice the main roads were blocked — once by a huge fresh landslide and once by a fatal car accident.

1 August Spent the day in San José.

2 August All the way back to Berkeley — 14 hours, thanks to a miserable layover in Miami.

Greene, H.
1987

16 August Tilden Regional Park, Contra Costa Co., California

I arrived at the miniature steam train ride $\approx 1400\text{ h}$, at the request of park naturalist Rachel MacDonald. The people who run the little train had complained of a group of rattlesnakes, so close to the tracks that they feared a snakebite and lawsuit. The man (lead by Eric Thompson) told me that they are not opposed to rattlers, but felt that these were a danger. Three days ago they saw two sparring upright with each other, presumably male-male combat, and earlier today two adults. We rode the train through oak savanna and chaparral, stopping at a rock pile beside the track. It was 3-4 m in diameter, $< 1\text{ m}$ high except for one large boulder, and encompassed a small group of shrubs. There was a pair of Crotalus viridis copulating in the shade of the shrub when I arrived, and the ♀ rattled furiously when I hoofed them into a bucket (next day, not in copulo, the male was more aggressive). We moved all the rocks we could, but found no other snakes. The rocks were more than 1 m from any passenger at any

Greene, H.
1987

16 August (continued) found, and in my view unlikely to have possibly caused a bite. I later gave the snakes to Ayako English, who relocated them to East Bay M.U.D. land nearby.

27 August Tucson, Pima Co., Arizona

arrived here \approx 1900 hr, having left Berkeley in my new Toyota truck yesterday at 1500 hr, odometer at 510.6 miles. It is 900 miles from my apartment to the home of D. L. Hardy, where I am staying.

28 August Lunch w/ Howard Lawler at the Desert Museum

30 August attended "shower" for Sylvia Laaster, who will deliver any day now, at the home of Jim & Linda Jarchio (he is a vet, specializes in reptiles). Met Bert Martin, studying Uroderma w/ Lowe, whom I corresponded w/ >10 years ago.

31 August Met Robert Robichaux at the U. of Arizona, my host for the sabbatical month here. He showed me my office space on Tumamoc Hill, introduced me to Paul Martin, etc. After dinner, I went hunting \approx 1900-2100 hrs on the western bajada of the Tucson Mountains and in the Arava Valley. A large thunderstorm in the western sky, but overheard stars and a $\approx \frac{1}{2}$ moon. Saw 4 Crotalus atrox (2 juveniles), 1 C. tigris, 1 C. scutulatus, and 1 C. cerastes; and 1 Bufo cognatus.

Greene, H.

1987

1 September Road hunted \approx 1900-2100 hrs on the western bajada of the Tucson Mountains and edge of the Avra Valley. Got 4 Crotalus atrox (2 juveniles), a small Lampropeltis getula, and a Bufo alvarius.

2 September Road hunted for \approx 1 hr w/ David Hard in an area SE of Tucson (near the E. part of Saguaro Natl. Monument) and got only a juvenile Rhinocerelus lecontei ("claus" phase - no red on snake).

3 September Cave Creek Canyon, Chiricahua Mts., Cochise Co., Arizona Asirocled here \approx 1500 hr - partly cloudy and almost cool. Talked to Barney Tomberlin in Portal and got moved in at the Hardy's house. W/ instructions from Barney I set out before dusk to look for Sistrurus catenatus in an area of "short grass prairie" (desert grassland?) \approx 20 mi. S. of Rodeo on Hwy 80. He says the best stretch is from the Rucker Canyon Rd. turnoff (which is 18.5 mi from the State Line) to a tree on the right side of the road (which is 6.7 mi from the Rucker Canyon turnoff). I traveled that stretch from \approx 1830-2045 hr, four trips, and saw:

4 Crotalus scutulatus (1 ad. escaped), 1 C. atrox (1 juvenile, not collected), 1 juv and 1 ad Pituophis melanoleucus (1941 & 1949 hr, not collected), and 1 ad Rhinocerelus lecontei. The two adult ♂ C. scutulatus were impressively dark brown and gold snakes, immediately reminiscent

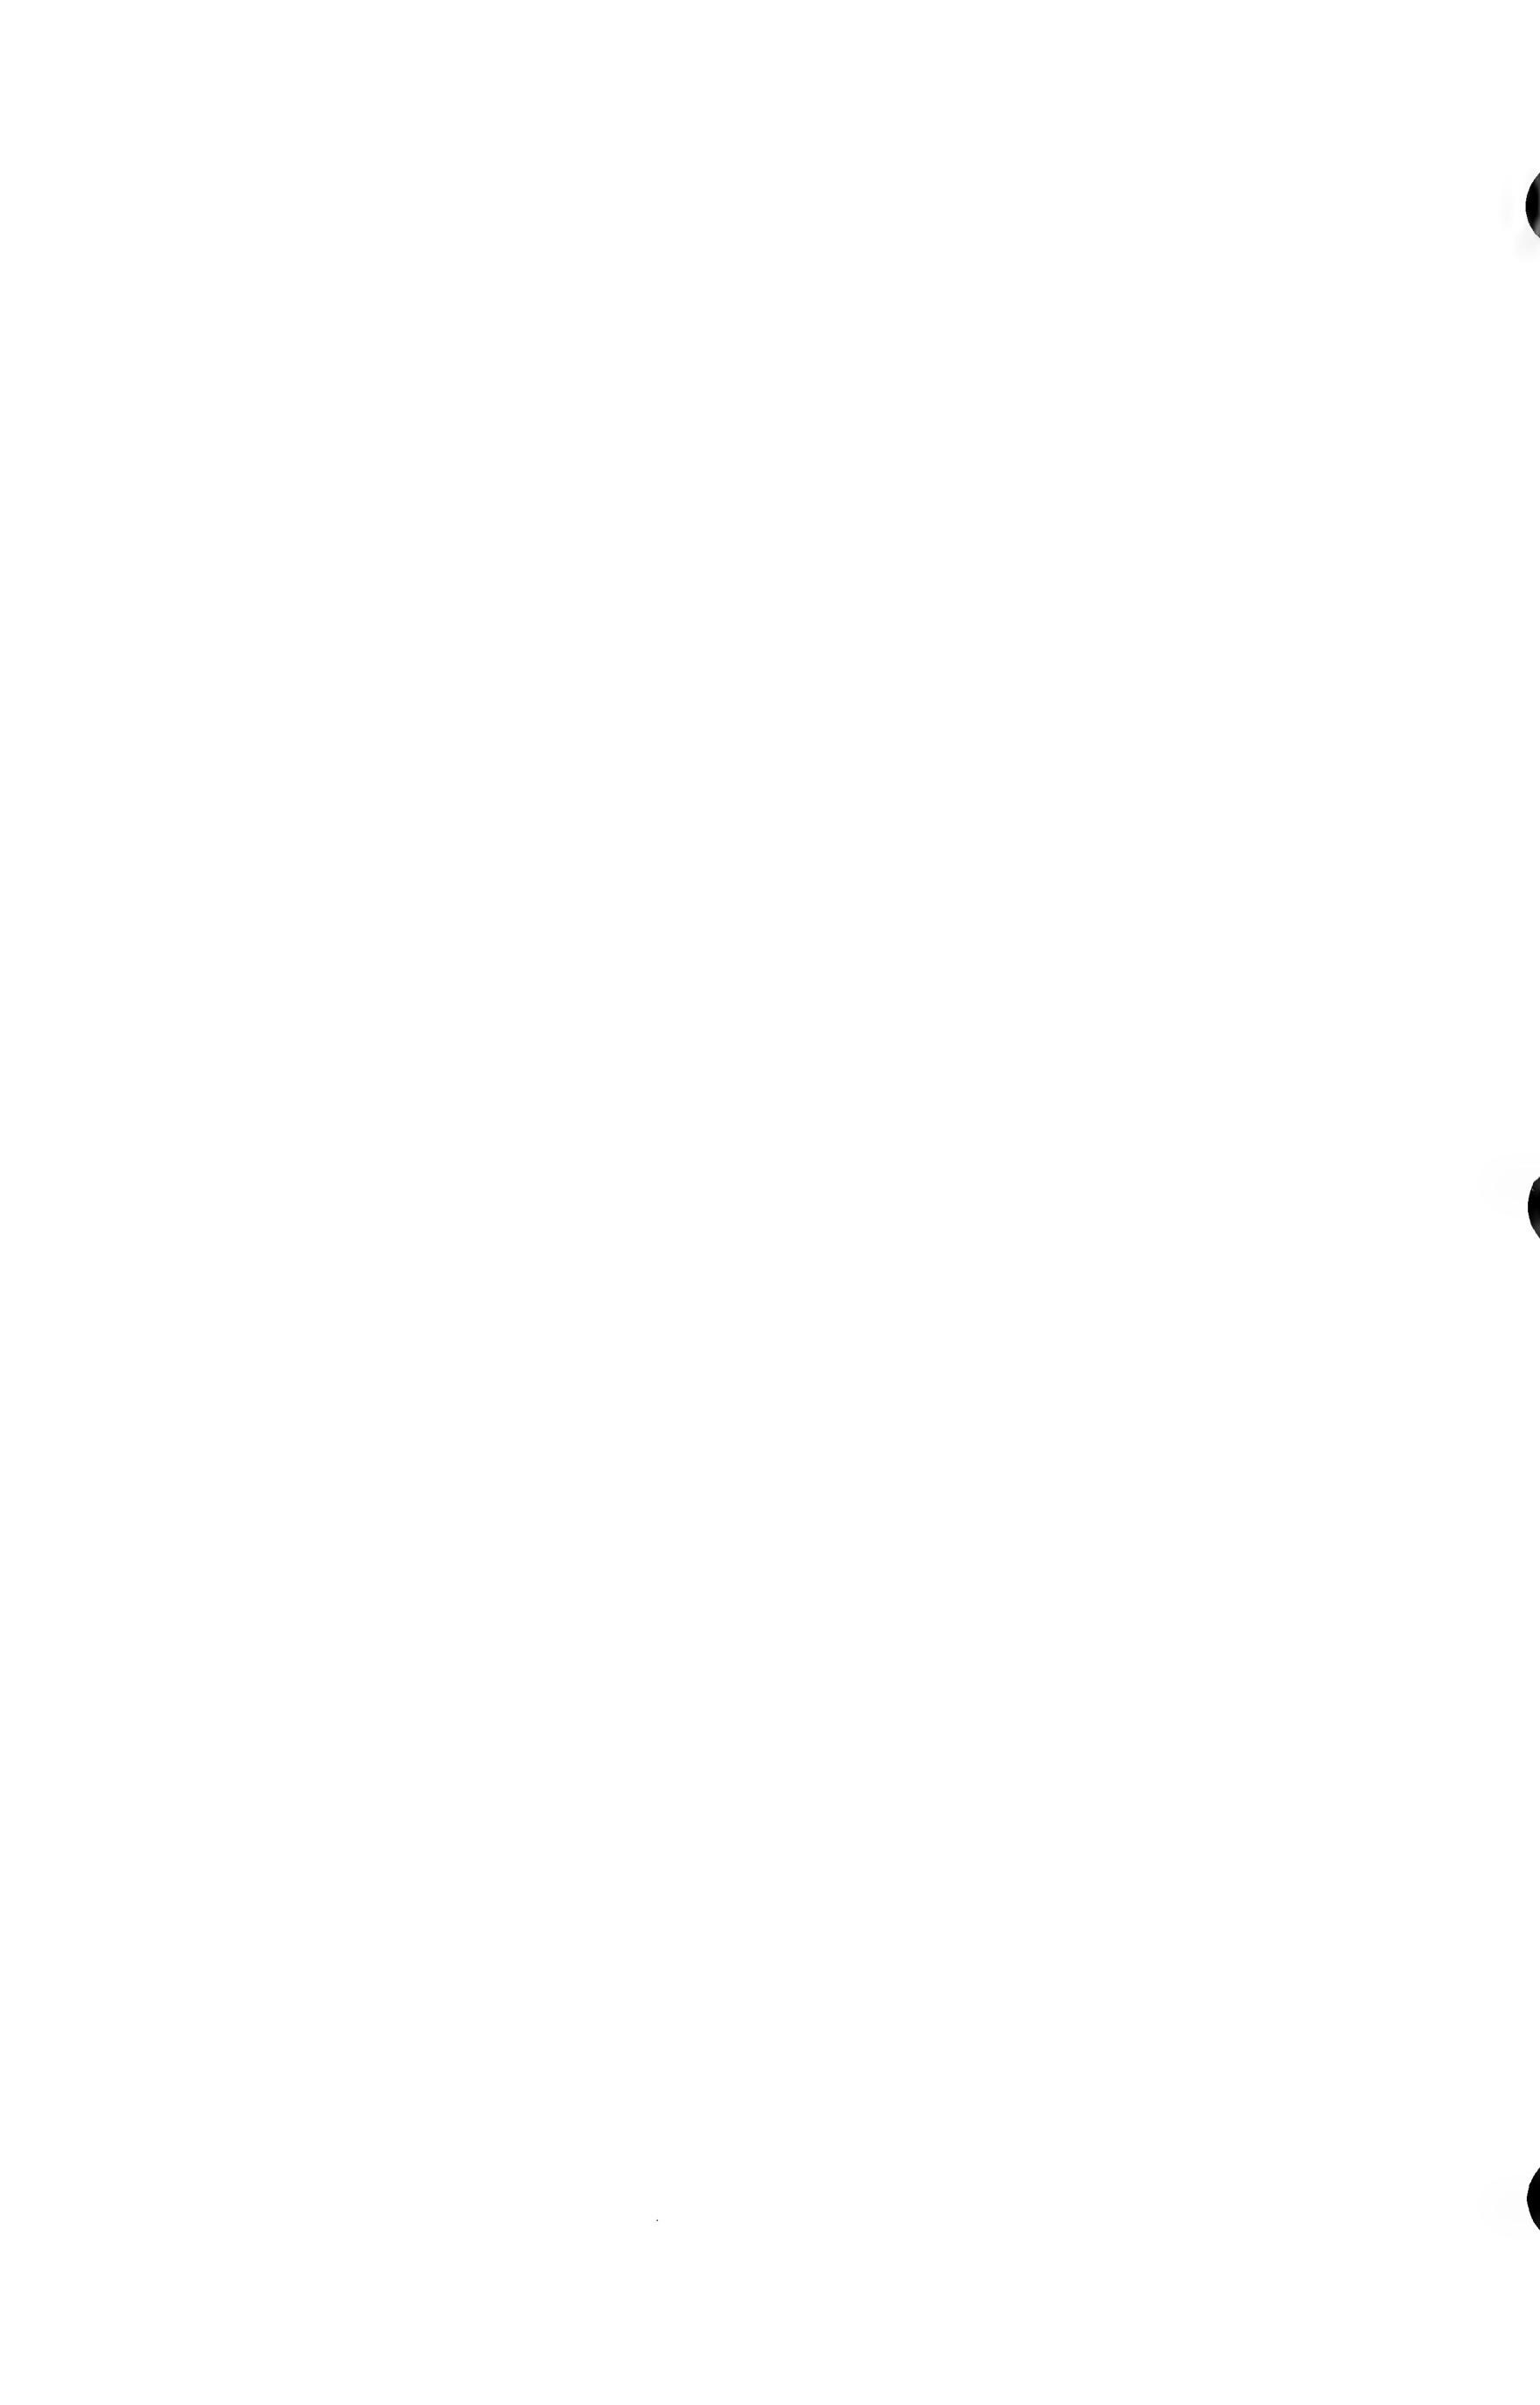

Greene, H.
1987

3 September of C. viridis. Both were very jumpy snakes:
(continued) coiling tightly, rattling, and jerking about when approached, and crawling rapidly away when I first tried to hook them into a bucket. One has a well-healed puncture scar at midbody. At 1800 hr I found a Tenapene ornata sitting w/ head out on the edge of (dirt) State Line Road; it excreted copiously, struggled, and snapped when picked up. After returning to Portal made one circuit up Cave Creek Canyon to the SWRS and back to the Hardy's House, but saw only a Megalitis and two fawns (together), no snakes.

4 September Dunch w/ Wade Sherbrooke. Overcast and cool all day in the canyon, with a shower at SWRS at noon. At 1630 hr watched Geococcyx hunting (evidently) on the rock wall behind the Hardy's house, under dense mesquite. The bird hopped rock to rock, pausing every few seconds, motionless except for tilting head as if inspecting the lower branches - and I have seen Crotalus ornatus on this wall. Went road hunting to the "Sistrurus site" w/ Barney Torberlin. Got 3 Thamnophis marcianus in a short stretch, and a juvenile Lampropeltis getula near State Line.

5 September Drove up the canyon in mid-morning (Cave Creek) and then out to the "Sistrurus site" to take pictures. Periodic showers and sun. Found a

Greene, H.

1987

5 September

Terrapene ornata in mid-lane w/ head outstretched?

(continued)

It "urinated" a foul-smelling liquid. \approx 600 hr
(after a hard shower) drove to SWKS and back w/out
seeing anything on the road, and hiked for \approx 1 hr up
the N facing slope at the South Fork turnoff. Turned
 \times 8-10 dead agaves, saw nothing. After dinner w/
the Hardys, Barney, and his friend Tony, Dave
and I went to the "Sistrurus" site "and back one
- saw an AOR juv Pituophis melanoleucus, AOR
neonate Crotalus scutulatus, and a well-dead
adult Thamnophis marcianus at the same spot
on the road where Barney and I got 3 two
nights ago.

Greene, H.
1987

25 November

La Selva Biological Station, Heredia Province, Costa Rica

Arrived in San José the 21st, and here \approx 1100 ps today.

A new season for me - in the capital, mostly sunny skies ("celeste" to the ticos), frequent moderate gusts of wind, and rain only infrequently. On the 23rd, went to the Teatro Nacional w/ Carmen Rojas and her mother to see Soledad Bravo - a Venezuelan singer whom I like and had learned of through a tape Carmen sent me. President Oscar Arias was at the theater, and we passed within a few meters of him twice. Sra. Bravo dedicated a Cuban song that I like very much to him. On the ride out today I was impressed with how rapidly "civilization" is growing in the Sarapiquí region. This really struck me in La Virgen de Sarapiquí, a really tiny hitching post where we used it as a jumping off point for the 1983 expedition into the Zona Protectora - now bustling with activity and construction. After lunch talked to Orlando Vargas, who told me he saw a Polyclitus in the same tree where he caught one last July - "perhaps the same one?" Then Mariellos Charazia took me \approx 20m on the CES to a Bothrops asper that Edwin Pangra had shown her - a truly gigantic ♀, at least in terms of head size. She is \approx 6-8m W of the trail in an old gap, asleep in a

Greene, H.
1987

25 November (continued) moderately tight coil, next to an old small fallen trunk or limb. The head is \approx 75-85 mm wide. I checked her three times w/ various people and took photographs between 1330-1400 hr, and she never so much as flicked a tongue. At 1743 hr, more or less dark, her head was up and over the outer coil, and she turned slightly to me when the light hit her. At ~~1807~~ 1907 hr she was \approx 1 m S of the resting spot, on ground between two limbs of the fork of the fallen log, facing \approx W and alert. At 2107 found an active Iwanthodes cenchraea \approx 2.3 m high in vine tangles among banana plants, just S or E of the Sara Bridge (on the old station side, 8.2 g, 53+23 cm, cf. ♀). At 2120 hr another Iwanthodes cenchraea a few meters from the first, at \approx same height (16.4 g, 65+27 cm, cf. ♀). Both snakes were ascending vines slowly when I saw them. When touched each crawled upward. Only response to handling was to squirm and to release a strong, sharp odor. At 2137 hr the ♀ Bothrops asper was still alert at the same position, undisturbed by several photos. Between 2107-2120 I checked the Cantarana Research Swamp, but couldn't quite get to the boardwalk because of water over the trail. Several kinds of frogs calling. Hard rain here on the 21st I'm told, and some this afternoon. Night clear.

Glenn, H.
1987

26 November left at \approx 0810 w/ Leslie Saul and Norman Gershwin (from San Francisco Zoo), went out the Near Joop to Carrizo Central 1800, then back across the El Suampo and in on Holdridge Trail for lunch at \approx 1215 hrs. Sunny but not too hot. At 0727 hr I had checked the ♀ Bothrops asper on CES, found her back in the "resting spot" with head facing \approx NE (as opposed to SE yesterday at rest). Saw various Norops, Dmeira, and a few Eleutherodactylus on the trail - plus of course Dendrobates pumilio. At 0950 hr Norm spotted an adult Mastigodryas melanomus motionless on the trail, w/ head up, after I had walked over it (1700 Carrizo Central, 87g, 73 cm + 24.6 cm, ♀). When seized, she struck repeatedly, spun rapidly about the long axis, and exuded a mild must. I palpated the head and fore-trunk of a Sphenomorphus cherriei (swallowed tail-first, x adult size) from her. At 1020 hr we found a Hadesis muta at c c 1800, as reportedly seen yesterday by José Miguel Alvarez. The snake looks to be \approx 1.4 m total length, and is coiled under a dry leaf but easily visible, with head facing the trail. It is \approx 1.5 m from the base of an adult (fruit pods) Welfia palm. No sign of awareness of us during photographing; might have a food lump. Saw tracks of at least

Greene, H.
1987

26 November Two felids in the swamps, at least one large
(continued) enough to be Panthera onca or Felis concolor.
at ≈ 1200 hr we heard a crashing in a banana tree
beside the sidewalk and saw the largest, darkest,
fattest wild Nasua narica I have ever seen - it
clamored to the ground, then ambled off leisurely
w/ tail up (this was just E. of the ^{Sura} ~~sura~~ Bridge).
At ≈ 1330 hr took pictures of the ♀ Bothrops asper - she
still in same place. At 1729 hr - still barely light,
even in forest, she is out alert in the "hunting site".
At 2009 hr she is in the same spot - both nights
head has been in same orientation to surroundings
and the neck is in a sharp S-coil. At 2150 hr,
a Micromys nigrocinctus crawling at moderate speed
off the trail at CES O (forest edge). As soon as I
gently restrained it w/ my boot the snake thrashed,
bit repeatedly, tail displayed, and crawled very
rapidly. When I gained the head in my hand
it tried to spin, musked, and repeatedly poked
w/ the tail spine. Very hard to hold. Tail was often in
a loose ring w/ tip overlapping, but never in a
tight perfect coil. I was impressed by how hard
it was to discern its bodily orientation, and how
the tail spine was a "threat" - first reaction was
to jerk away from it (?).

♀ Bothrops asper still hunting at ≈ 2200 , not
disturbed. Today was Thanksgiving, and

Greene, H.

1987

26 November (continued) tonight we had a fantastic meal: sheets for a "white table cloth," red wine, turkey, excellent dressing, mashed potatoes, brown gravy, and apple and pumpkin pies. Everyone ate 'til they groaned.

27 November at 0828 hr as I walked to w/in \approx 2 m of the ♀ Bolitoglossa asper, an Ameiva festiva (small adult) spooked and ran over her. The big snake jerked her head alert and I quietly slipped back to the trail, hoping she wasn't disturbed enough to move sites - she is back in the "resting place." at 1130 hr she is still there.

at 1148 hr Roberto Cordero showed me a Leptophis depressirostris crawling in grass in front of Cabina #1 (mine). He said it had advanced on him, but he didn't notice the mouth open. When I seized the snake, it spun several times, attempted to crawl away fast, and thrashed laterally, but never gaped or bit. It defecated while being measured (65g, 695+400mm). at 1627 hr the B. asper was still at rest - forest shady, but still easy to see. I watched her from 1713-1745 hr but she never moved, although it was quite dark by the time I ran out of tolerance for the mosquitoes and went to dinner. I was surprised to find her still "resting" at 1955 hr. at \approx 2010 hr. Jerry Rovner (Ohio U., spiders) called me to a ♀ Basiliscus

Greene, H.

1987

27 November plumifrons asleep \approx 2 m upon a Heliconia leaf
(continued) in front of the main lab (115g, 151+454 mm).
She struggled, gaped, elevated tongue, and tried
to bite when seized.

28 November Sick all day, \pm have been several other people.
Upset stomach, headache, weak and sore muscles.
The ♀ Bothrops asper was coiled in the "resting"
place at 1100 hr and 1550 hr, but not visible at
either site at 2100 hr. Where is she? Not pleasant
looking for her at night... Beth Newell saw a
juvenile Micruroides (?) by her cabina after
dark.

29 November Feel better this morning. At 0750 hr I found the
♀ Bothrops asper back in her resting site. When
I moved leaves near her head, she jerked her
head up and in my direction and froze - no
tongue flicks, tail movements, etc. I slipped
away, and returned at 0757 to find her quiet
again. From \approx 1030-1300 hr walked the CCH and
CCC with Carmen Rojas. At \approx 1330 I found the
B. asper at her "resting" site, then walked to
500 m on CES and back, to 500 on SOC and
back, and checked the B. asper again \approx 1500 hr.
Walked in the Cantarana swamp from 2100-2130 hr
and saw a few Ibyla roquay and one small
Agalychnis callidryas, and photographed some
spiders, including an arboreal ~~tarantula~~ tarantula.

Greene, H.
1987

29 November (continued) As we headed for the CES, I dropped in the back door of the "new lab" to tell Jerry Rorner about the spiders, was in there < 2 minutes, and when I came out ran right into an adult ♀ *Bothrops asper* crawling across the door mat by the boot rack! Hooked her onto the smooth porch, then required \approx 10 minutes to get her into a trash can. She changed directions rapidly, often sliding a body length or more in an instant. At least once she crawled more than a meter at me. Several times she advanced up my hook, and once I had to drop it. Never vibrated the tail, never gaped, and never struck. Always seemed very alert, nervous, ready to go at me. At 2150 I failed for the second night in a row to locate the huge ♀ *B. asper* on CES.

30 November At \approx 0710 I spotted the big *Bothrops asper*, coiled under the fallen log, less than 1 m from her site 2. She was also there at 1400 hr (head has changed position), 1650 hr, and 1945 hr. Between \approx 1100 - 1200 I photographed two iguanas in a tree by the N. end of the bridge, a big orange ♂ basking and occasionally head-nodding on a large branch, and a smaller (but longer than

Greene, H.
1987

30 November "yearling") green (♀?) on a limb above
(continued) him. Second Iguana never moved, except
to gape w/ raised bright red tongue (very
obvious from a distance) after some time in
direct bright sun. After lunch, the smaller
was not to be seen and the large one was
somehow attached vertically to a slender
branch in dense dry foliage. As I crossed the
bridge, noticed numerous Rhinocerosmys basking
on logs. There is a large tree w/ log jam
around its crown remnant, extending from
the south bank to about midstream. It
is ≈ 200 m downstream from the bridge and
has been there some time. At 1300 hr today
there were 4 Rhinocerosmy, a butia
longicaudus, and an adult Iguana on
this logjam — the big lizard on the outer
most limb and thus in mid-stream. No
evidence that it or the other regarded each
other as anything — or wasn't it the right
habitat for an attack? At ≈ 1700 Beth
Newell was on the phone and stunned to see
a large calf in the clearing near the short
trail that goes to the arboretum! Checked the
Cantarrana Swamp ≈ 2030 hr but heard only an
occasional frog. Very bright sky, no rain
in days.

Greene, H.
1987

1 December

Absolutely cloudless blue sky as I walked over to breakfast. The big orange Iguana was still suspended (precariously?) vertically on a branch w/ heavy foliage. The adult ♀ Bothrops asper was under the log (site 3) at 1045 hr. Between 0700-0800 hr a small (and somewhat skinny looking) ^{adult} Micruroides alleni was found near the Comedor/Reception building on the north side of the river [this snake dead morning of 2 December 1987, with palpable evidence of broken back, preserved, HW & 1700]. Checked Bothrops asper ♀ after breakfast and after dinner and she was under the log (site #3) both times. Going to lunch I noticed that there are two orange iguanas in the tree, the one mentioned earlier identifiable by its slightly regenerated tail tip - the other is really large.

From ~1315-1700 hr walked with Rebecca Butterfield and her husband David to the Rio Beje and up it for a few hundred meters. We saw ~~too~~ numerous tracks of small felids, and I collected 6 scats, most or all of a large felid - these varied in age from 1 very fresh to very old. They showed me where twice in one day they saw an adult Caiman crocodylus and her young together. This was at the bridge over a little stream that crosses the Sendero El Atajo. Both times, she slid in and swam upstream then waited, while the ~30 youngsters scattered among vegetation downstream. At ~1630 hr

Greene, H.
1987

- 1 December I saw a Lepidoblepharis xanthostigma crawling in
(continued) leaves on the trail.
- 2 December Another sunny day, although fog at dawn. The ♀
Bothrops asper was still at Site 3 after breakfast.
She was also there at mid-afternoon and after dark. Alejandro
Solorgano arrived this afternoon, and after dark we walked the
Sendero Oriental out and back w/out seeing anything. Orlando
Vargas brought me an Enulius sclateri he found DOR in
La Guaria. At \approx 1900 hr Rebecca Butterfield discovered a
freshly dead juvenile B. asper (HWG 1701) on sidewalk by
the Villa Esperanza, apparently stepped on unseen by
someone. Alejandro and I killed and pickled the big
B. asper I caught 29 November, because the Clarks
preferred it not be released near the building or elsewhere.
- 3 December Alejandro and I left before 0800 and walked out the CCC,
Camino Central, Sendero Sur, and back on the Holdridge,
arriving at the station \approx 1130 hrs. At 0828 hr we caught
a juvenile Mastigodryas melanolomus (♀ 300+100 mm, 9g)
crawling off the trail into leaves - twisted about
long axis, thrashed, and bit repeatedly. At 0900 hr
we found the Lachesis muta at CC 1800 in exactly
the same place I saw it 26 November. Three people
checked this spot on the 27th without seeing the
snake, but I suspect it was there. It is a young ♀,
1260+123 mm, 950 g. Very calm until after we
handled her, then quite brava. She crawled
slowly w/ the body extended, head in a tight S-

Greene, H.
1987

3 December coil, and anterior third greatly inflated. No tail (continued) vibration. Struck twice. We steered her back into the cavity under the leaf. I allowed as how since the only two trail segments I'd never walked at La Selva were Linderio Sur to Holdridge and back and since surely the distance wasn't much greater --- in fact, the Linderio Sur in that part is hill after hill, all very steep! just before one reaches the corner of the property (which requires one last killer hill) the trail crosses the Quelroda Esquina, a likely look spot for Atelopus if there are any at La Selva. The outermost \approx 1.5 km of Holdridge are also made up of steep trails, then there's 200 m of bad mud and no bridges. I fell into mud-high once and narrowly missed being skewered on an old trail stake. We saw a dark animal bolt across the Holdridge, almost certainly an Cira barbara. We saw a Butra longicaudus dive in the Quelroda Esquina where it crosses Holdridge at \approx \$H01000. Saw several Felis sp. tracks in the mud on that trail. Started raining \approx 1030 hr and rained off and on the rest of the day, never hard. The big ♀ B. asper was still in the same spot after dark. We saw almost no frog activity in the Cantarana Swamp, but caught a neonate Inmantodes ceciliae resting coiled on a leaf \approx 30 cm above forest floor at \approx CES 150 (1.7 g, 236+96 mm).

Greene, H.
1987

- 3 December
(continued) Only response to handling was to squirm, crawl rapidly, and eject a drop of liquid (clear) and a tiny chunk of uric acid from the rect. I could detect no odor. At ≈ 2300 hr Deborah Clark caught a juvenile Clelia clelia ($482 + 101$ mm, 26.5 g) in front of their house on the sidewalk. Its only response to handling was to crawl and squirm, and eject and odorless liquid from the cloaca.
- 4 December Rained off and on all day. At ≈ 0800 hr Alejandro and I caught the big ♀ Bothrops asper without much difficulty - she seemed not especially alert and simply dashed here and there in the dense ground cover around the logs, never striking. Pinned her twice, once to put in the trash can and once to measure her (2.15 Kg, $1610 + 220$ mm - see below). After the second pin there was blood in her mouth, which we assumed was some trivial cut from a fang. When released she crawled under the log and seemed OK. At ≈ 1100 I located her stretched out nearby, with the head turned awfully and a fly on it, but she turned toward me when I touched the tail. At ≈ 1400 hr I found her in the same place, dead, slightly stiff. Re-measured her as $1721 + 225$ mm, substantially larger than we thought. Pickled her. Skin appeared "old," so we wonder if we aggravated some existing condition or simply fatally injured her? At night I noticed a Hyla glaucochroa eating bugs on the outside of the bathroom window - attracted

Greene, H.
1987

4 December
(continued)

There by the light inside. Not much frog activity in the swamp (Cartasara) despite the rain.

5 December

at \approx 0800 Beth Newell and Roberto Cordero saw a Epiplatys punctatus in grass beside the walk at Villa Esperanza, which crawled up a nearby sapling at forest edge and froze on a horizontal limb. As soon as I seized it the snake vibrated the tail and struck and thrashed powerfully (680g, 1540+510+tip missing). When released \approx 3 m from forest edge it crawled rapidly into the woods. Did not fully inflate throat during handling, but body was always inflated when I held her (?). Saw only Hyla elracata and another small hylid in the Cartasara Swamp, and a large crab in the water.

6 December Lots of rain, all day. Only walk was with Carmen Rojas out the Sendero Occidental and back - saw nothing.

7 December

At 0627 hr, on the way to breakfast, there was an Eia barbara behind cabina #1, perhaps after fruit on the ground. It moved quickly into the forest as we approached. Walked out and through the arboretum from \approx 0730-0830 hrs. At 0757 hr a Mastigodryas melanolomus was crawling rapidly in leaf litter beside the trail (δ 285+83 mm, 6g). It thrashed and bit repeatedly (hangson), and I palped a lizard egg from it. When released it assumed an elevated S-tilt and struck rather than crawl away. Today is sunny, clear, warm. Next I photographed

Greene, H.
1987

7 December (continued) a Brachyphus in a small Cecropia near the south end of the bridge, over the river (occurs to me that this might be an especially safe place for it to sleep). Saw three Iguana iguana in vegetation & trees near north end of bridge — a large orange-spined male alone, and the male w/ partly regenerated tail along with a (he?) green smaller (♀?) animal about 2 m away. The large submandibular scales of the males are always easily visible, and they often have the snout elevated. From ≈ 1450 -1600 I walked the Senderos Oriental and Occidental, but saw nothing.

8 December Sunny all day, no rain. At 1007 hr Jorge Vega (brother of Gerardo) showed me a spider eating an anole, ≈ 2 m up the trunk of a spiny palm in front of the main lab. The spider was an adult Cupiennius getazi ♀ (file J. Rovner, Ohio University). The lizard was an adult ♀ Norops limifrons ($41+88$ mm, 1.15 g, non-gravid). Lizard was still struggling weakly when I found it, but the spider seemed to be easily holding on.

Jerry told me he recently saw a Nephila clavipes eating a lizard here too, and a Cupiennius eating a frog. At 1930 hr Deborah Clark found an adult ♂ Micruurus nigrocinctus (the one I saw earlier? I don't think so...) on the sidewalk in front of Cabina #3. When touched it crawled rapidly into the grass, and when pinned it thrashed the body, thrashed the tail more rapidly —

Greene, H
1987

8 December coiling and uncoiling but never holding a "ring."
(continued) When handled and palpated it twisted violently, writhed the posterior and repeatedly "pricked" me with the tail spine, and expelled a strong smell. Crawled rapidly away when released.

9 December The guard reported a Bothrops asper adult the last few nights along the sidewalk to the River Station, so I spent ~30 minutes after breakfast looking for it without success. Saw only a juvenile Norops capito. Overcast. Going to San José today to celebrate Carmen's birthday.

10 December Instituto Clodomiro Picado, Costa Rica

Spent the day here but didn't take any photographs because the shutter on my camera locked and I stupidly thought it was broken - later proved to be only a bad connection w/ the battery! Saw a Dipsas articulata said to probably be from Puerto Viejo de Sarapiquí. Very slow to react, but with some poking it assumed a rigid, exaggerated "viper" pose, with quadrates expanded (NB: does this occur in Sibon? Seen occasionally in Ninia - nice example for phylogenetic analysis). An Erythrolamprus marmoratus from an unknown locality (with a bright orange nape band) body flattened, hid head, thrashed elevated coiled tail. Another behaved similarly, w/ the addition that its hemipenes were both partially held erected during the tail display. Also, an enormous

Greene, H.
1987

10 December
(continued)

Xenodon rabdocephalus that was very aggressive
— striking w/ wide open mouth out of its cage.

11 December

Ta Selva Biological Station, Prov. Heredia, Costa Rica

Returned today by O.T.S. vehicle. This morning Orlando Vargas encountered an adult Lachesis muta coiled on the north side of the trail at $\approx 870\text{m}$ on the Sendero Suambo. At ≈ 1400 I walked out to it with Feynner Godinas, Deborah Létourneau, and two friends of theirs, Laura Harnish and Judy Appel. We found the snake in a loose coil at the edge of the trail (not actually on it), with head resting on an outer loop and possibly alert. I estimate its length as 1.7 m. — adult but not large. Afterwards we returned by way of the Senderos Suambo and Holdridge, in moderate rain all the way. Stopped for a swim at the waterfall, and I started to climb out the first time the rope broke and I fell butt first on Judy's head — a first for us both! As we were clambering about in surprise, Feynner swam up with a large adult ♂ Norops oxylophus caught on wet rock face beside the falls, so the five of us had an impromptu lesson on ankles while chattering — teeth and dog paddling. Finally pulled out with some difficulty.

12 December

at ≈ 0645 I left with Renaldo Aguirre and Vivien Solis to see the Lachesis muta at S. Suambo 870, but it was gone. I searched surroundings w/out seeing it. Gave an hour lecture in Spanish to the workshop on environmental education here.

Greene, H.
1987

13 December

J. Rorner brought me a neonate Nothopsis rugosus that he found this morning ~~in~~ exposed on the ground in leaves, near the sidewalk to the River Station, just into the woods from the new laboratory (105+50 mm, 0.8g, umbilical scar present). The ground color is a brighter light yellowish orange than I have seen in other specimens. When he seized the snake it went semirigid, such that he thought it dead. When I restrained it, the snake vibrated the whole tail slowly, alternated squirming w/ rigidity, and emitted a strong odor after several seconds of handling. At 2105 hr his student, Renee, (see 17 December 1987) called me to an Oxyrhopus petola crawling under the stairs of Cabina #2 (12g, 375+82 mm). When handled later for photographing, this snake thrashed in place and waved the thrashing (not looped) tail, stopped abruptly at times, and emitted a foul odor - overall effect moderately like a coral snake.

14 December

at \approx 1400 hr David Clark brought me a neonate Crotalus annulatus, found by a cleaning man on a rotted log of Cabina #2 (465+92 mm, 18.5g, umbilical scar present). When handled it only crawled normally, occasionally pulling the head back into a striking coil, and twice half-heartedly gaped and/or struck at my finger. During the day someone left an Inantodes cenchroides in a bag on my desk (10.5g, 603+261) - only reaction to handling was frantic crawling and emission of a very foul odor. From \approx 1930-2100 hr walked the Sendero

Greene, H.
1987

14 December
(continued) Occidental w/ Feynne, Deborah, Laura, and Judy. Saw two Potos flavus high in trees, lots of tiny Hyla and lots of Eleutherodactylus diastema calling (today was sunny and bright very clear - lots of stars, but we had a hard rain \approx 0530 hr.). At 2015 hr an adult Inonotus inornatus, frozen as it crawled up an aeviad stem from a fallen log, \approx 1.5m above the ground. Log was in dense second growth beside trail, amidst bromeliads, vines, etc. ($707 + 115 + ?$ (tip missing) mm, 36 g). Only reactions to handling were crawling, thrashing, and emission of a mild odor. At \approx 2100 hr I spotted a ♀ Norops capito ($82 + 135$ mm, 12.5 g, ova palpable but small). She was on a leaf \approx 20 cm above the ground in forest, and struggled, gaped w/ tongue elevated, and bit when held.

15 December As I crossed the bridge from breakfast at \approx 0645 hr I noted an adult ♂ Bradypus variegatus in a Cecropia tree just W. of the bridge on the S. bank of the Rio Puerto Viejo - I saw a sloth (same?) there yesterday afternoon, and have seen a male of similar size there at least 6 times (days) since arriving here in November. When I returned at \approx 0920 hr I saw the sloth move out a limb and eat fresh-looking fruit. At \approx 0930 hr I spotted a Urocarpus longicaudus in the middle of the main limb of the large fallen tree that extends N-ward into the river \approx 200 m downstream. At times the otter lay on its side, evidently to groom, as I saw the head placed against the rump, shoulder

Greene, H.
1987

15 December
(continued)

and inguinal region. The latter appeared more pinkish and slightly swollen, causing me to wonder if the animal is a ♀. It then made several complete circles on the limb, pressing its chin and chest lower than the hindquarters - scratching, marking, both, or what? From time to time it peered upstream w/ head and foreparts raised, at which time the distinctly lighter throat (and chest?) was very evident (social signal?). It eventually stretched out against another horizontal limb, facing into the sun and apparently basking. Before settling down it once abruptly moved to a limb that forked upward basal to the main limb, turned and in some manner lifting the tail - defecating, urinating, marking, or what? The otter remained visible for \approx 10 minutes, then abruptly disappeared into the water. ~~This~~ Carmen and I started to walk S.

off the bridge and saw an adult ♂ *Bradypus variegatus* climbing the bare trunk of the *Cecropia* at \approx 2x normal (i.e., compared to previous observations) speed. At first I thought the first sloth was ascending again after an unseen trip down, but now saw it at the top of the tree, suspended under a leaf. The second sloth ascended the tree continuously, and quickly reached the first animal without deviating on any side branches. ^(\approx 5 were possible) As it arrived it reached for the other w/

Greene, H.
1987

15 December (continued) a forelimb and they began grappling — soon (within seconds) a writhing mass of sloth arms and legs, all accompanied almost from the instant of first contact by series of sharp, short, high-pitched cries, coming from one or both of the sloths. Within 15 seconds, the first was hanging by hindlimbs and the second was pulling or falling free from the limb. They were suspended as such for a few seconds before the second broke free with the first still swinging at it w/ forepaws. The second descended the tree continuously at $\approx 3 \times$ "normal" speed and disappeared in vegetation from which the Cecropia emerges over the river. When the second broke free, the first hesitated a few seconds, then descended the limb rapidly (this as the second was still in view) to the crotch, then veered out a limb over the river and began to feed. When I crossed the bridge for lunch there were no sloths in the tree. I had the strong impression the "intruder" saw the "resident" before I first spotted it going up the trunk. The speed of movement was especially impressive, ~~and~~ no more than 2 minutes were passed between when I first saw the intruder and its exit; ~~and~~ the encounter ended at 09:41 hrs.

16 December At 0830 hr I located a ≈ 1.6 m? Bothrops asper

Greene, H.
1987

16 December
(continued)

at SOR 830m, \approx 80m past the big "bat tree" Dipteryx, that Feynner Godivas encountered last night. He saw her alert and coiled out on the trail, whereas now she is in a tight coil under surface green vegetation just off the cleared trail and a few cm from a small tree. There is a large treefall \approx 3m away. The head is down and in (see photos), more like is typical of Lachesis. I returned in a rain at \approx 2030 hr w/ Carol Farneti of Partridge Films, and found the snake out "hunting," about 25 cm from the base of the small tree and in the cleared trail, facing the boardwalk. Alert - turned and tongue-flicked when in light. At 2048 hr, as we returned over the same route, I found a \approx 1.3 m Bothrops asper at SOR 220m. The snake was in a moderately tight coil, w/ head and neck in 5-coil pointed at the boardwalk. Caught a gravid ♀ Eleutherodactylus fitzingeri near the lab in wet grass after dark (SV 45 mm, 6.5g).

17 December

Walked out SOR and around the CCC-CCN loop w/ Carol. Missed a small adult Mastigodryas melanurus as it dashed off the trail at \approx CCL 700, 0919 hr. I slammed my left forearm onto a spiny palm trying to catch it. Couldn't find either Bothrops asper from last night on the SOR. At 1514 hr I found a Leptophis ahaetulla lying motionless on the cement floor under my cabina ($\text{♀ } 820 + 515 \text{ mm}^{66.5g}$)

Fraene, H.
1987

17 December (continued) The snake thrashed, spun, struck, bit, gaped w/ wide open mouth, and emitted a foul odor when seized. When later released on a sapling it glided deliberately up and out of sight. Palped from it the remains of a hylid, cf. Smilisca, w/ nest to heel of 40mm. It had faint crossbars on the thighs, which had their posterior surfaces unicolor and separated from the dorsum of the thighs by a sharp border that becomes a white line across and over the anus. Frog had been swallowed head-first. Examined feces of Arythoporus petola collected 13 December, and found only many small reptile scales that I took to be Dmeiva festiva. At 1600 hr David Clark caught a Rhadinaea decorata ♂ on the sidewalk by my cabina (253 + 50 + ? mm, 7g). When handled it squirmed, exposing repeatedly the red ventral ~~and~~ colors, and emitted a very foul odor. I palped 3 pieces of tail of a Sphenomorphus cherriei, which fit each other perfectly. At 1950 hr in a light rain I found a neonate Leptodeira nebulosa ♂ in above ground on a broad leaf, next to the sidewalk near my cabina. It squirmed and smelled slightly, but no biting or gaping; when I palped 2 tiny transforming, unidentifiable frog heads (cf. hylids?), swallowed tail-first (snake 4.6g, 274 + 16 mm, distinct umbilical scar). At 2026 hr, near the turnoff

Greene, H.
1987

17 December
(continued)

To "Rafael's House" on the SOR, - spotted an adult Leptodactylus pentadactylus. When we stepped closer, I could see something bloody protruding \approx 30 cm from its mouth - and for a moment I thought about the possibility I had somehow stepped on it and this was the tongue, yet how could it be so long? At that point the frog began regurgitating, and as I seized the prey it finished vomiting and hopped out of sight. The dead prey was a ♀ Imantodes cenchoa (605+291 mm, 19g, HWG 1705), with at least one spinal fracture and a large piece of skin ripped at midbody and intestines protruding ventrally. The snake seemed dead, but most of its tail was coiled tightly around a stick \approx 20x2 cm - probably the only reason the frog hadn't already swallowed it when we arrived. At 2039m I met an adult ♀ Bothrops asper crawling down the muddy trail by the big Dipteryx tree at SOR 750 m. She froze briefly in the light, crawled another few meters down slope, then turned W. into the forest. All crawling was rectilinear w/ the body almost straight, and the snout was frequently tipped downward as she tongue-flicked the litter. I held my snakestick over and parallel to the snake, and thereby estimated total length at 1.7 - 1.8 m. Because of apparently greater girth, I don't

Glebe, H.
1987

17 December

(continued)

I think this is the same snake I saw yesterday only
≈ 80 m away, but she is very similar in
color pattern and hue (very yellow).

18 December

On the way back from breakfast, ≈ 0730 hr, saw
3 green ibises (Mesembrinibis cayennensis) perched
on the downstream logjam in the Rio Puerto Viejo.

I was impressed by their dark iridescent
feathers, blue-green legs (almost lagoon-like from
a distance), and long light curved bill. At one
point two gathered and engaged in two bouts
of bill "shacking". Eventually, one at a time but
w/in less than a minute of each other, they
flew low across the water to the north bank and
disappeared from our view. I could see
clearly a fresh pile of otter shit on the big
emergent log right under the bridge — so
bright reddish and irregular in texture as to
look like a flower. Clearly like others I've
inspected, filled w/ crustaceans. As we watched,
John Blake told me he once saw an Iguana
iguana swim leisurely across the river
here, sculling with its tail. Carol Farneti
and I walked the CES & CEN then out
to the end of the SOC but saw nothing
but a few Norops. Rained most of the morning,
and almost seemed cool. By noon the
river was so high that the log under the

Greene, H.
1987

18 December bridge was invisible and the log jam almost
(continued) submerged. David Clark showed me a
big ♀ Brodryps variegatus right next to the
bridge, and many photos were taken. After
lunch there was intermittent sun and I could
see a large ♂ Iguana iguana on each bank
of the river and opposite sides of the bridge -
I'd guess 75-100m apart. They were each very
easily visible to me, and I wonder how far
apart they can see each other? Rain again in the
^{Valverde} afternoon. Jose Miguel ~~Alvarez~~ brought me a Bothrops nasutus
that he found on the CCC, and which was "my brown"
(28.5g). Walked to the end of SOR and back w/ Carol
Farneti and Carmen Roldan - saw 1 Agalychnis saltator
and several Hyla elaeochroa in the Cantarana Swamp
and at least 4 adult Leptodactylus pentadactylus along
the SOR. At 2032 hr we found a small Imantodes
cenchoa ≈ 0.8m above ground beside the SOR, near the
turn-off to "Rafael's House" (3.9g, 424 + 190mm). When
first discovered, the snake was extended upward at
a steep angle, such that ≈ 30cm was in space. After
gaining the next stem, it hung out over a flat green
leaf and tongue-flicked its surface without any
actual contact or movement of the leaf.

19 December Rained off and on all last night and this morning -
at times very hard. After breakfast there was
sporadic sun as I crossed the bridge. There

Heene, H.
1987

19 December was a large ♀ Bradypterus griseus in the Cecropia
(continued) tree on the south bank - and watching it I am
now sure the ♂ I watched earlier was eating the new,
red leaves - not fruit. The river is still up, but
I saw 2 sun grebes (Heliornis fulica) downstream
near the river's edge, in the muddy water. There were
at least 4 adult iguanas on the NW bank - "short tail"
in a tree well in from the shore (as he often is) and
three in high foliage along the river. Two of those were
big, orange spined males and one was a little
smaller and all dark gray-green. I saw at least
1 orange-spined ♂ on the SW bank at equivalent
height and (orange-spined ♂ on the SE bank
out on an open tree limb at ≈ same height. All
had their dewlaps out and I think they were all
in mutual view (took photos). At least one on
the NW bank periodically head-nodded. I was
stuck by how visible they are in profile at a
distance - surely they are thermoregulating, but I
also had the strong impression they were
advertising. Rained all afternoon and into the evening.
At ≈ 1940 hrs I spotted a ♂ Iwanthodes cenchroides (676+ 330 mm,
14.5 g) crawling slowly through a vine tangle in front of
cabina #1, about 2 m above the ground - stomach empty,
so presumably hunting. Walked to CES 500 and back but
saw only Hyla elaeochroa. Walked through the Cantaiana
swamp, where there is a huge chorus of Hyla

Greene, H.

1987

19 December (continued) elaeochroa, a few Agalychnis saltator, and a single Smilisca baudini calling. I found an Ivantode inornatus ($610+253$ mm 19g) $\times 3$ m over the east end of the boardwalk, crawling down a very slender, dead-end limb, with neck ^{body = $\approx \frac{1}{4}$ TL} extended straight along limb. Palped from it a freshly ingested Hyla elaeochroa, swallowed tail first, 1.8g (pickled). The snake responded to handling by squirming and emitting a foul odor. At 2140hr, in a low bushy tree near the west end and just north of the boardwalk (same tree from which last summer I retrieved an I. inornatus containing three frogs), I found a large ♀ I. inornatus (43g, $700+285$ mm). It was in a loose coil, w/ head and neck possibly extending back up into the tree, at the end of a leafy branch about ≈ 2 m above the water. From it I palped a gravid ♀ A. saltator that had been swallowed head-first, 60 mm heel to anus, >5g. Response to handling was squirming, emitting a foul odor (this accompanies ejection of a viscous liquid and a small quantity of uric acid), and pulling the head into an S-coil w/ quadrates spread - very reminiscent of Dipsas sp. No striking - only response to additional poking was crusting. We found a juvenile Hyla rufilata on a broad leaved plant ≈ 1 m above ground, near the sidewalk into the swamp.

Greene, H.
1987

20 December Still raining off and on this morning! At 0656 hr a workman showed me a juvenile ♂ Bothrops asper in wet grass beside the sidewalk just north of the bridge, but it crawled rapidly into the vegetation. Rained all day and night. There was a Christmas party, complete with "discororit" - a disc jockey with sound system - and attended by many local ticos and their families. At \approx 2200 I went to the Contarana swamp to release an Dermatodes inornatus and found four more! Rain was so hard I had to take two back to lab to process them (wouldn't reach the others, etc., because they were in the off-limits area). There was a huge chorus of Hyla elachistoa, plus a few each Aeglychnis saltator and H. microcephala, a Smilisca baudini, and several very loud Gastrothecae pictiventris - the latter calling from in water. At 2205 hr. an L. inornatus \approx 1 m above water in a tangle of leafy vegetation (640 + 241 mm, 25.7 g); has a healed ventral scar at \approx ventral scale #50. It squirms and emits a foul odor - in fact, as with all of this species I've handled, when first touched the cloaca is prolapsed and gaped while a little fluid and uric acid is expelled. Palped 4 Hyla elachistoa, 3 recently swallowed headfirst w/ weights of 1.8, 1.8, and 2.0 g; and one swallowed tail - first of which only the head remains. At 2240 hr I saw an adult (\approx maximum size) L. inornatus

Greene, H.
1987

20 December (continued) crawling very slowly in some broad leaved plants that arise from a large stump, such that the snake was \approx 1.6 m above water. This snake I watched until \approx 2253 hr, and it crawled continuously over and between leaves. It moved over a leaf w/ head and neck on the leaf, seemingly sweeping and not avoiding contact as in D. cenchroa - my impression was that it was behaving like Leptodeira septentrionalis, and using the extensible neck to bridge gaps but not to search without touching leaves. The tongue was protruded frequently. At 2055 hr. an D. microstomus \approx 0.8 m above water in dense leafy tangle (small leaves), crawling slowly (741 + 283 mm, 37.3 g ♀). Reacted to handling by squirming, cloacal prolapse, and emission of a foul (nauseating) odor. Palped two Hyla elaeochroa, freshly swallowed head first with a number of fresh green, jelly-less eggs (2.1, 2.2 g). These were cf. A. saltator. At 2315 hr I could no longer see the second snake, but found a fourth, $\approx \frac{1}{2}$ adult size, \approx 30 cm over water among stems of the large aquatic-emergent plants. Squirmed and emitted foul odor when handled, stomach empty. Raining very hard now, and seemingly the harder it falls the harder the frogs sing!

21 December cloudy with hints of sky as I walked to breakfast - and two ♂ Iguanas iguana already visible although it's overcast. By 0800 hr there is bright sun.

Breue, H.
1987

21 December (continued) at 0955 hr I was called to an adult Leptophis depressirostris \approx 2 m above ground on a limb at the clearing edge, in woods. It was immobile, started to crawl when I reached for it, and thrashed, spun, and gaped once briefly when seized. But my leg as I palped a frog from it. Snake 698 + 407 mm, 58 g. The Leptodactylus pentadactylus was only a few cm distal to the snake's head and made feeble movements when touched (2.25 g, HWG 1722); swallowed tail-first. Left for San José at 1300 hrs.

28 December Returned to La Selva \approx 1100 hr, after a week in San José w/ Carmen Rojas and her family for Christmas. In my absence the little Bothrops nasutus bit and killed the Corallus annulatus and Oxyrhopus petola, among seven snakes with which it was caged. After dark on the 23rd, Jerry Rovner encountered an Oxyrhopus petola on the sidewalk near the main lab that rapidly climbed \geq 3 m up a small tree in its attempt to escape (HWG 1723). At 0945 hr today David Clark caught a juvenile Xenodon rabdocephalus in front of my cabina (#1) that gave him an "impressive display" and regurgitated a small Leptodactylus pentadactylus (HWG 1724, 1725). I palped a second, partially digested L. pentadactylus from the snake \approx 1400 hr, swallow TF, and allowed it to be reingested. This little Xenodon responded to the approach of a hand by rapid lateral undulation w/ body and head not expanded,

Greene, H.
1987

28 December
(continued)

during which it looked very much like a Bothrops asper neonate. When coaxed but not touched, it coiled w/ neck in S and tail coils and slightly elevated, and struck repeatedly and rapidly in succession - again reminiscent of B. asper, but when in a coil, between strikes, the quadrates were spread laterally as were the anterior-most ribs, creating an impression of a much larger head.

Jeny Rorner and Renee (?), his student, saw a gigantic Spilotes pullatus on the Holdridge Trail, adjacent to the parades. It froze at their approach, vibrated the tail and faced them w/ inflated throat, then moved off into the forest. Renee thought it was 12-14 feet long, Jeny 10 feet - when I told them the one we photographed a few weeks ago was 6'9", they were surprised it was that long and felt that based on much greater girth their big one was at least 10 feet and maybe longer. Oh how I'd like to have seen that snake! After dinner I gave a talk on predator ecology to a group of Wisconsin U. students. Rained most of the night.

29 December

Rain and lab work all day. From \approx 2000-2050 hr walked out the CES with Carmen. At CES 85, 2010 hr, a very small Bothrops nasutus (161+17 mm, 4.3g) coiled tightly on a palm leaf \approx 65 cm above ground and next to the trail. Snake would have had to climb \approx 45 cm of stem from ground; palm next to a small old

Greene, H.
1987

29 December fallen limb (photos). I touched the outer coil lightly (continued) w/ a stick, intending to gently slide it into a bag, whereupon it catapulted off into the leaf litter - seemingly w/ a single flex of the body. My image was of a broad S or J-shaped projectile. Hit the litter crawling and went under the limb, from which Casmen poked it with snake stick. More frantic crawling, perhaps sidewinding at times. At 0830 hr next morning I palpated two pieces of tail, swallowed head-first, of Sphenomorphus cherriei. While handled for measurements and palping, it struggled and tried to reach me with fangs.

30 December Rain during the night, until dawn, sometimes hard. From 0930-1115 hr walked to Holdridge 900m and back, then out ^{to} the arboretum. Saw only a Micrastur mirandolii, which flew across the path and perched on a low branch. At noon a great blue heron downstream. From \approx 1530-1700 hr walked to Holdridge 750m and back w/out seeing anything - rained hard, with shining in brightly from the west at the same time!

31 December From 0900-1100 hr walked out SOR, out CCC to \approx 200m past the Saltito Bridge (?), back to SOR and out Holdridge 900m and back - saw only Cebus. Michael Fogden walked to the south boundary and back without seeing a snake! He brought me a fresh small Felis scat from Sendero Suampos \approx 500m.

Greene, H.
1987

31 December (continued) At 1300 hr we could see a dead adult ♂ Iguana in the river, bloated and hung on a snag, some flies on its emergent right side, legs dangling in the water. I couldn't see a tail tip so wonder if it is "short tail" whom I haven't seen for days. Downstream on the N. bank I can see at least four adult ♂ Iguana, all very visible and out over the river. The farthest is at the W bend, ≥ 400 m away, and I first glimpsed it without binoculars (or glasses!). I noted 4 adult ♀♀ in a tree with one, at least one with another. Carmen and I went back at 1500 h. The especially large orange male, upstream on the south bank, is visible out over the river and displaying periodically. In the next tree toward the bridge we counted 7 adult Iguana, 1 young adult ♂ and 6 ♀♀! Further upstream from the orange ♂, there was a small adult ♀ at the top of a dead snag, ≈ 10 m up and at an angle out over the river. Thus today I saw at least 18 different adult iguanas along maybe 500 m total shoreline, and I surely missed some! And, there are many more in from the river, as we have seen them in numbers just west of the comedor. Also, saw a little blue heron on the downstream logjam at noon. Rained very hard for a half

Greene, H.
1987

31 December hour at noon, lighter off and on in the afternoon. As we started across the bridge at dusk for dinner, a Caluromys derbianus was fairly running up a high cable on the bridge and then nimbly climbed off to an adjacent tree, where it descended out of sight in foliage on the south bank of the Rio Puerto Viejo. I picked up the eye shine of an adult Caiman crocodylus near the north bank and slightly downstream, then saw it approach, contact, and move (bite) the dead Iguana carcass. As we started up the bridge from dinner, saw a (the same?) C. derbianus rapidly scale a tree and run out a limb tip, turn back, and disappear into the foliage. I am repeatedly impressed that this opossum is more agile in trees than Didelphis. At 2000 hr we met for the Christmas Bird Count, and totaled 325 species! [Next morning the Iguana carcass was gone, but I don't know if it was eaten or washed downstream. On 2 January 1988 I saw "short tail" in his old haunt, and now wonder if the dead lizard had washed down from upstream?]

Greene, H.
1988

1 January To Selva Biological Station, Prov. Heredia, Costa Rica
We had planned to leave today and spend the next few days in Monteverde, but problems with car rentals caused us to decide this morning to remain here until the 6th, for the sake of fewer hassles and more total time spent enjoying the forest - this after spending most of the morning packing! At lunch a visiting bird watcher told me that yesterday, he saw an adult Iguana iguana on the ground w/ a brown snake snake in its mouth - he felt unsure as to whether was trying to eat the snake or just kill it. In the afternoon I walked to SHO 900m and back, with a sidetrip to CCL 700m, without seeing any snakes. A visitor told me he saw a coral snake that was unequivocally Micruurus nigrocinctus struggling with an unidentified brown snake in the morning.

2 January Rained hard most of the night and intermittently in the morning. I walked to SHO 900m and back, with a side trip to CCL 700m. At 0959 hr. at SHO 250m I grabbed a skinny - feeling Chironius grandisquamis as it moved rapidly off the trail into "plot" vegetation (♀, 1260 + 735 mm, 468g). The snake thrashed, inflated the anterior $\approx \frac{1}{2}$ of the body, and repeatedly struck when seized. While being palpated and measured,

Greene, H.
1988

2 January The cloaca was prolapsed and it oozed a thick
(continued) yellow liquid. I didn't detect any odor. Walked
to CES 700 m, and spent \approx 10 minutes at \approx
CES 550 m searching the area where I saw two
Lachesis muta in July 1987. Lastly, ~~we~~ went
to \approx 250 m SOC and back by \approx 1130 hr. At 1855 hr.
Collin Nichols-Orians led me to a large Leptodeira
annulata crawling slowly up cobbles under a
wheelbarrow ramp to the north end of the Rio
Puerto Viejo bridge (\pm 635 + 158 mm, 109 g). When
seized, she crawled rapidly and released a very
foul smelling liquid from the cloaca. Carmen
and I walked to CES 700 m from 1930-1830 hr
but saw nothing - a dry, bright moonlit night.

3 January From \approx 0830-1100 hr Carmen and I walked out
the CES, LOC, Sendero El Atajo, and down to the
Rio Sarapigui. I found an old hulia
longicaudus scat on the rock I've often seen them
on before, and the end of the Sendero Ribeño.
This scat contained large fish scales and parts
of crustacean exoskeleton. On the porch of a
casita at the origin of Sendero El Peige I found
an old dry and a very fresh small cat scats,
possibly Felis pardalis. Maria Marta Charania
uses this house to sleep in when she collects
butterflies, and tells me a cat often defecates
there. At 1312 hr. I found a juvenile

Greene, H.
1988

(see next p.)

3 January, Scaphiodontophis venustissimus in the trail to
(continued) the Sendero Arboreum from the AC Trail (217+130 mm,
9g). The snake was motionless until seized, and
quite cryptic despite its velvety coral snake pattern
and bright yellow (leaf-like?) head. When grasped
it crawls rapidly and wraps the tail around
anything in reach. At 1312 a Prof. Green from
University of Colorado, studying Paraponera,
showed me a juvenile Bothrops asper in a
tight coil under the edge of a rotten fallen
limb (σ 325+50, 12.4g). Snake's head was
parallel to limb's long axis, thus ideally situated
to intercept a passing prey. When I scarcely
touched him with a snake hook, the fangs
turned instantly and bit. Struggled and bit
when handled to measure, etc. At 1241, just
after lunch, I checked trees behind ($\approx w$) of the
conveyor and spotted a pair of Iguana iguana
mating. They were at least 8-10m above ground
on a mat of foliage and limbs at the edge of
a rank clearing, in an area where I have
always been able to spot adults over the past
few weeks. When first noticed they both had
their heads pointing $\approx S$ and sides toward
me, except that the σ 's head was crossed
over the φ 's shoulders to the right. His
body was largely on her left, but arched

Greene, H.
1988

3 January around so the vents were at least nearly in
(continued) contact - I could not see if they were actually
copulating. There was a second adult ♀ \approx 2 m
away in the same tree. At 1246 hrs. the pair
separated - the ♂ remained immobile, raised
on forelegs and facing me, with orange "roach"
of spines erect and dewlap out. The ♀ walked
 \approx 1 m away (\approx S.) and more or less simultan-
eously she and the other ♀ began eating
green leaves in a seemingly "unconcerned"
manner. Forgot to state earlier that I palpated the
tail and pelvic region of a Sphenomorphus cherriei from
the juvenile (it has a visible umbilical scar) Scaphiodes typicus
venustissimus; the skin had been swallowed
head - first and had a hind leg (to heel) length of
10 mm.

4 January Left at \approx 0815 hr with Carmen for \approx CC 400, where Ron
(new ad. asst. director) saw a Bacchus muta late
yesterday afternoon - in fact, he told me it was
at CCC 400 m so I dash out there at dusk, only
to learn later of the mix-up in trail designation. He
reported the snake as at the 400 m sign, on the W.
edge of the trail - we found it at 0900 hr, on that
side but at 420 m on the CC. - evidently asleep
and in a loose coil. Based on size, bright
coloration, and even sleeping posture I think
it likely this is the same bushmaster I saw

Greene, H.
1988

4 January / 11 December 1987 - a "young adult" perhaps 1.6-
~~(continued)~~ 1.8 m total length. Returned by way of the CCL
and SOR, but saw no other snakes. A warm,
sunny day. The last couple of days Iguana have
seemed much less commonly visible from the
bridge, an impression reinforced as I crossed
back and forth for lunch. From \approx 1430-1600 hr I
walked out SOR to SHO 800 m and back.
Released the Chironius grandisquamis at the capture
site at SHO 250 m. In trying to get it to stay
put for photographs, I had to haul it out on
the trail 7 times before it (tired?) took up a
stationary defense posture - neck in elevated,
exaggerated S-coil, quadrates spread laterally,
and mouth slightly open. It would make
short strikes if approached closely, or swim
and swing to bite if seized, but otherwise
held the S-coil and oriented the entire elevated
coil as I moved around it. When I retreated a
few meters to put away camera gear, it waited
 \approx 1 minute then crawled into the adjacent
"successional plot." In retrospect, there are two
other reasons to suspect that the Lachesis muta is
the same one earlier seen nearly on the Sendero
Swamp: it is in a loose, open coil; and it is
on the trail edge, potentially exposed to sun - in
fact, this morning it was in a sun flack

Greene, H.
1988

4 January such that I took photos first without flash. However,
(continued) I recall a few other instances (e.g., the first Lachesis
I saw at La Selva) of open day coils. A cloudy
but moonlit night - I made two circuits around
the lab clearing sidewalks without seeing
anything, after dark. A visitor saw an adult
Microtus nigricinctus at dusk, on the path
to the Old River Station.

5 January From 0900-1030h I walked to CC 420m and
back, by way of the Camino Circular and
Sendero Oriental. Rained at night until dawn,
and a cloudy, humid but cool morning. Found
the Lachesis muta in the same spot but with
head facing south, unlike yesterday. Going to
bunches I could spot the large orange ♂
Iguana iguana on the SE bank of the river,
2 ♂♂ near the bridge on the NW bank, and
1 ♂ at the river bend downstream - and
one N. of the river near the volleyball court
- but I still have a feeling things are calming
down for them. After dinner, I walked to the Old
River Station, out SOR & CCC to the back side of
Sendero Cantarana, through it and out the CES to
300m, then around the lab clearing and out onto the
river bridge for one last look for Polycladus in the
adjacent trees. This was between 1945-2120 hr,
right after a brief shower. There were scattered

Greene, H.
1988

5 January (continued) frogs calling, but I saw no snakes. The moon is more or less full, and the forest is well lit anywhere there's a hole in the canopy.

6 January Spent most of the morning packing - leaving la Selva today for San José and the C. S. a beautiful ride out - bright blue skies, white clouds, and the green slopes well lit in the afternoon sun.

8 January Carmen got my export permit this morning without problems. I went to the Instituto Clodomiro Picado with Alejandro Solozano, where he gave me 2 baby Bothrops nummifer, born in captivity, a gold B. schlegelii from the Pacific slopes, and a peach-colored B. schlegelii that only reached the Instituto today from south of Herón. Alejandro told me that B. lateralis is the snappiest arboreal viper here, and as he was telling me that the one I was looking at on a hook made a fast strike at my face that ended with a "flash gape" for an instant. Photographed an Emelias from near the institute. In the afternoon I talked with Federico Bolanos, who gave me a scat or stomach content of a B. schlegelii (59.6 cm, 122g, UCR 10231, Finca La Palma, Dos Ríos de Upala, Prov. Alajuela, 5 November 1987).

Greene, H.
1988

19 March North Coast Preserve, Branscomb, Mendocino Co., California
arrived here \approx 1800 hr yesterday w/ 23 students in a UC Berkeley Herpetology Class, plus TA's Kevin de Queiroz and Jon Llorente, ^{and} Hart Welsh (U.S. Forest Service). By that time today we'd found 19 species of herps. We went to two sites for Ascaphus on Elder Creek in the morning, and to the "White House" at edge of a meadow in the afternoon. In addition to herps, we saw a pignut owl (Glaucidium), ~~feast~~ tracks and scat of Ursus americanus, and tracks of Felis concolor. I saw several scats, cf. Tonyx rufus. The herps were:

Bufo boreas - under rocks near Wilderness Lodge.

Rana boylii - several along Eel River and Elder Creek.

Hyla regilla - several under rocks and many heard calling in late afternoon. At one short stretch of trailside in woods, we found 5 ♀♀ on a sun-dappled roadbank; w/ \approx 10 m. all gravid.

Ascaphus truei - 2 small ♂♂ in a side tributary of Elder Creek.

Dicamptodon ensatus - numerous larvae, some very large and obviously neotenic in the creek behind Wilderness Lodge.

Rhachophorus olympicus - several adults and larvae in side seepages of Elder Creek.

Taricha granulosa - Several under cover items in woods.

Batrachoseps attenuatus - " " " " "

Greene, H.
1988

19 March

(continued)

Aneides ferreus - a few, under cover items in woods.

Aneides flavipunctatus - " " " " "

Ensatina escholtzii - many, of all sizes and including at least one gravid ♀, under rocks and logs.

Clonophis macrostomus - 1 in Eel River.

Eumeces skiltonianus - several under cover objects.

Elgaria coerulea - many " " "

Elgaria multicarinata - 2 under logs by a lone old tree at edge of meadow by White House, same place we got this species when I was here two years ago.

Echelognathus occidentalis - many, in sun.

Thamnophis elegans - 1 crossing trail near river at $\approx 1400\text{m}$, tried to escape down hole under root.

$198+65\text{ mm}$, 3.8 g , regurgitated adult

Batrachoseps attenuatus, swallowed head-first
tail autotomized, $38+42\text{ mm}$, $\approx 0.6\text{ g}$

Thamnophis sirtalis - 1 crossing trail $\approx 1230\text{ m}$,
 $375+131\text{ mm}$ ♀, 21.7 g , regurgitated the
autotomized tail of an adult Batrachoseps
attenuatus.

Diadophis punctatus - 2 under boards near the
White House. One, $165+30\text{ mm}$, 1.4 g , regurgitated
an autotomized tail of an adult Batrachoseps
attenuatus, $\approx 0.3\text{ g}$, $\approx 32\text{ mm}$.

Greene, H.
1988

20 March Ore Springs Rd., between Comptche and Ukiah, Mendocino Co.
Stopped for \approx 45 minutes at abandoned mill site, 6.2 mi E. of Comptche - saw Anelides flavopunctatus,
Sceloporus occidentalis, Hyla regilla, and two small Thamnophis elegans. At a steep ravine
 \approx 3 miles further E., we got numerous salamanders including Taricha rivularis, giving a grand
total of 20 species of herps for the trip. Beautiful weather entire weekend!

Greene, H.
1988

July 31

Portal, Cochise Co., Arizona

arrived here in mid-afternoon with Missy Wood, having spent the previous two nights with David and Billie Hardy and two days before that driving from Berkeley. Went road hunting at ≈ 1830 hr to the Sistrurus area, ≈ 18 -25 miles SW of State Line Rd. on Hwy 80. Found a large adult, very light-feeling Pituophis melanoleucus stretched out and motionless just SW of the little bridge at the base of the curve/hill that Barney Tomberlin says is best for Sistrurus. Snake made an exaggerated S-coil, hissed loudly, and struck when I touched it with snake hook. Let it go. Collected a juvenile Lampropeltis getula, which only crawled and squirmed when seized; a small Crotalus scutulatus that crawled in a frenzy, rattled, and struck when restrained; and a freshly hit adult C. scutulatus in the same area. Saw several Scaphiopus couchii and some Bufo on the highway.

August 1

Picked up several frozen snakes from Barney Tomberlin. Good rain at midday. Cool and overcast all day. Road hunted from ≈ 1900 -2230, up into canyon, back through Portal, several passes through the Sistrurus area and again through the canyon (to South Fork). Saw only a live Crotalus scutulatus (collected), and a DOR Thamnophis marcianus near the Sistrurus curve. Numerous

Greene, H.
1988

- August 1 (continued) Bufo cognatus and Scaphiopus on the road and calling, and one Rana (pipiens - type) in Cave Creek Canyon.
- August 2 Woke up once during early morning to solid rain. Cool and overcast all day. Roadhunted to the Sistrurus site - saw no snakes.
- August 3 Last night Barney Tornberlin gave me a Tantilla yagouia that he caught at night by the Telephone Co. building in Portal. He offered it a relatively large Scolopendra which it killed but didn't eat - there was a wet, crunched little site and the centipede was still moving when we examined it. Got some good photos of it this morning - the head is tan anteriorly, with a black head collar and bold light supralabial spot. The light tan head is not mentioned in Stebbins' account (actually, it looks khaki). From \approx 1000-1200 hr Missy and I drove to Paradise and back, stopping at the Paradise Cemetery and a hillside to view rocks and look around. Saw a big Sceloporus clarkii in a rock outcrop crevice, a juvenile Crotaphytus collaris on a small roadside boulder, and several small striped Crotaphytus at 1147 hr a small adult Masticophis bilineatus escaped off the roadside into dense mesquite. It was sunny and partly cloudy this morning, so \approx 1400 we went to South

Greene, H.
1988

August 3
(continued)

Fork picnic area and hiked up and back the trail until \approx 1530 hrs. Increasingly cloudy, but we didn't get rain until \approx 1700 hrs. Saw several Sceloporus jarrovae. At 1500 hr I saw an adult ♂ Leiocephalus personatus crawling under the end of a small fallen mossy log beside the trail. The site is open woodland with lots of grass and rocks, only a few meters from the creek. When I seized and lifted the snake it thrashed and emitted a sharp odor, tho I saw no visible cloacal discharge. As I handed it to Missy it bit her, then me and attempted to swallow my thumb. No palpable food. The snake is aberrant in two respects. There is much fusion of black bands, such that posteriorly the red is eliminated; anteriorly, the red is restricted to paired lateral spots. The light bands - which tend to strain yellow, as does the snout - fuse at the vertebral margins to form irregular stripes. The snake was not especially obvious crawling in the leaves. During later handling the snake briefly assumed an S-coil, vibrated its tail, and made a short strike. After dinner at the Portal Store w/ Barney Torberlin, Tony Snell, and Charlie Painter (New Mexico Game and Fish), Missy and I road hunted in rain to State Line Rd. and back - saw

Greene, H.
1988

August 3 (continued) Bufo cognatus, Scaphiopus couchii, and S. multiplicata (several of each) and a large, freshly flattened Pituophis melanoleucus.

August 4 Sunny and partly cloudy this morning. From $\approx 1130 - 1530$ hr, Missy and I walked a $2\frac{1}{4}$ mile trail that ends at Herb Martys Dam and begins at a point on the road to that dam called Greenhouse Trail. We saw Sceloporus jarrovii and S. virgatus, a golden eagle, a fresh fox scat and several possible bear diggings. A few hundred meters past Ash Spring the trail crosses a small stream, and a few meters farther on the left (north?) is a large ($\phi \approx 1\text{ m}$) log with most bark gone. On the underside, a few cm above the ground, I noticed what later proved to be a small adult ♀ Crotalus molossus - at first I saw only the yellow posterior and black tail (was she thermoregulating with it?). Getting closer I saw her head facing out of the crack - she was between a firmly attached piece of thick bark on the underside of the log. She moved out of sight despite my efforts to hook her out, and I at first thought she went into the very deep leaf litter under the log. Spotted her back in the crack and after considerable poking got her crawling out a side hole. There was continuous rattling from the time I first touched her with the hook. At that point I could see her crawling out, and noticed another blacktail's head

Greene, H.
1988

August 4
(continued)

Peering out the crevice in my direction. Caught the ♀ w/out difficulty - she continued to rattle when hooked into a bag, but never struck. After some poking the second snake - a much larger ♂ - emerged a few inches from the crack and struck twice at me - short strikes from a tight neck S-coil that flashed a whitish mouth. He then retreated into the crack, but in doing so his tail came out and I grabbed it. Then hooked him out and into a bag after he滑ed off the hook a couple of times - he alternated holding ground w/an S-coil w/ suddenly crawling away rapidly, rattling all the time. Had them in the same large bag in my pack, and they quieted down immediately. Still sunny walking back to the truck, but dark clouds over the higher peaks. By ~1800 hr, back at the Hardy's house, I hear thunder and the valley below is very dark. Hard rain into the night. We road hurried from Portal to State Line Rd. and back, and saw a huge Rana catesbeiana, a few Bufo cognatus and Scaphiopus couchii, many S. multiplicatus, and 2 Bufo debilis - the live one (a ♀) defecated pellets full of ant heads.

August 5 Partly cloudy w/ scattered showers, some sun. Mid-morning we went past South Fork on the Care Creek Rd., stopping to search talus slopes and a meadow.

Greene, H.
1988

- August 5 Then drove down to State Line Rd. for some photographs.
(continued) Missy spotted a long-dead cow, now moistened enough by the rain (I suppose) to have attracted 6-8 turkey vultures. After lunch at the Portal cafe & a rest, we hiked the Ash Spring - Herb Martyr Dam trail - to retrieve missy's water bottle and take a sample of bark from the log where we caught the two Crotalus molossus. The site is shown as right on the 6100' contour on a topo map. Saw only a few Sceloporus jarrovii and S. vittatus. Thunder and dark clouds over the peaks as we walked out, and later when we stopped at the Cathedral Rock Vista Point there were scattered raindrops. Ran into Ed Heske (former MVZ student) over dinner at the Portal Store. Road hunted up Cave Creek Canyon to the SW Research Station and out 25 mi E. of Portal, but saw only toads and 1 juvenile Crotalus scutulatus.
- August 6 Bright sun and blue sky when we awoke, and for the first time saw Urosaurus ornatus and Sceloporus clarkii on brick walls of Hardy's house. Road hunting on Portal Rd. we saw a neonate and adult (≈ 1 m) Crotalus atrox (no food in either).
- August 7 Took Missy to Tucson airport, then road hunted over Gates Pass (Tucson Mts.) and out Sandario Rd. in the Avra Valley. Saw only an adult Bufo alvarius.

Greene, H.
1988

August 8 Had truck serviced in the morning. Did laundry and visited w/ Hardy's in the afternoon. \approx 1930 Howard Taylor and I drove to \approx 10 miles beyond Sells on Hwy 86 and back. Saw a few Scaphiopus, several Bufo alvarius, and one B. retiformis. Snakes includes an adult and juv. Crotalus scutulatus (latter not saved), C. atrox, C. cerastes, & C. tigris, Rhinoceriles lecontei, Dipsosaurus elegans (not saved), and Pituophis melanoleucus (not saved).

August 9 Spent last night with the Taylors and arrived back in Postel by midafternoon. I drove in by way of San Simon and Paradise, a beautiful ride. I hit a Physosoma douglasi that was basking in the middle of the road near Paradise, in an area of grassland and scattered junipers. Gerald Merker (Placesville) gave me a pair of Crotalus molossus he found in contact in the road at Stewart Camp in Cave Creek Canyon. I road hunted to the Sistrurus site and got only three snakes, one of them an aberrant Crotalus atrox. The snake is an adult ♂ that evidently lacks black and white on its body - ground color and blotches are blurred, although the tail rings are \approx normal.

August 10 Barnay Torberlin, Tony Snell, and I left \approx 1030 hr for a site we visited a couple of years ago for Crotalus pricei, at \approx 8100' el. and $\frac{1}{2}$ air miles E. of Barfoot Lookout. Sun was shining brightly

Greene, H.

1988

August 10
(continued)

this morning, but by the time we parked the peaks were in clouds, it was chilly and misty, and there was thunder. Rocks were very warm to the touch, however, and we saw a few Sceloporus virgatus and S. jarrovii active on rocks. We searched an E. facing ~~rock~~ rock slide w/ scattered outcrops, oaks, and stunted conifers - mostly open habitat w/ scattered thickets of some low shrubs. I encountered two ♂ Crotalus molossus w/in 5 min. at \approx 1135 hrs., both of whom I heard rattling before I saw them. The first was in a defensive coil, in the open but near rubble and shrubs. It rattled continuously, repeatedly crawled away (sometimes backwards, w/ the head in a short fine S-coil), and made short wld open strikes at least twice. Second snake was a few meters away, in a cavity between two adjacent rocks, and scarcely visible - I would surely have passed except for the rattle (or gotten bitten reaching in the rocks' crevice!). The second snake is an even larger adult, equally aggressive - also struck several times. Later proved to contain a rabbit, Sylvilagus (I released the first snake). On the opposite (\approx W facing) slope (which is wooded w/ large conifers, has lots of old fallen logs on grassy slopes), Tony found an adult ♂ C. pricei under a large piece of

Greene, H.
1988

August 10 (continued) rusty fin from which I palpated the hindquarters and tail of an adult Sceloporus jarrovii (sawed the lizard, released the snake), as we drove to the Portal Store for lunch, found a large non-gravid ♀ Physignosoma modestum basking (up on legs) in the middle of the road \approx 100 meters W. of the store - habitat is mesquite grassland. Road hunted to Sistrurus site, where I got a DOR S. catenatus that looked to have been hit \leq 1 hr earlier, also some Scaphiopus, an Azima DOR, and a young ♂ Crotalus molossus 2.0 mi E. of Portal in mesquite-grassland - although there are hills and ledge systems w/in less than a mile (I later photographed the site). This snake rattled continuously, struck, and struggled fiercely when pinned.

August 11 Partly cloudy when I awoke at 0730hr. Drove to 2 mi N of Paradise and back, hoping for Elaphe or lampropeltis in the riparian woods along East Tashay Creek. Retusing, I saw a large Crotalus atrox crawling out onto the dirt road 1.5 mi. N. of Portal on the dirt road to Paradise. Snake crawled rapidly back off road into heavy mesquite, moving \approx 10m before coiling, rattling all the time, after considerable struggle and some then

Greene, H.

1988

August 11 (continued) wounds for both of us. I hooked the snake out, back up onto the road, and into the bucket. The animal appeared very stout so I thought perhaps it was a gravid ♀ and/or contained a large prey item. Dave and Billie Hardy arrived \approx 1300 hr, and Dave and I measured the snake: a ♂ w/ no palpable prey, 1.85 kg, tail 97mm, total length \approx 1.42 m - a large diamondback by local standards. Every time I worked the snake, it inflated, crawled rapidly away, and when restrained formed a tight S-coil and occasionally struck. It also musked heavily, but I never saw any cloacal discharge. Yesterday Ed Heske (former UCB grad student) told me he found a D&R Hypsiglena torquata in mesquite E. of Portal that contained a Holbrooki.
Dave and I rode hunted from Portal to the Sistrurus area and made five passes over the \approx 5 mile stretch that seems best: we got four live snakes, one each Thamnophis marcianus (exaggerated S-coil, striking, and foul cloacal discharge), Crotalus scutulatus, Rhinocheilus lecontei (thrash, cloacal discharge), and Sistrurus catenatus (immobile, but later rattles for long stretches whenever I approached the cage). Driving back we released a large (\approx 1 m) Crotalus atrox that was just crossing onto the road.

Greene, H.
1988

August 12 Billie, Dave, and I spent the morning driving to East Whitetail and Jhus Canyons, on the northeastern side of the Chiricahuas - saw only several Sceloporus jarrovii, and the skeleton of an adult Pituophis melanoleucus beside the small stream in Jhus Canyon. After an early dinner, Dave, Basney Tom Berlin, and I rode hunted to the Sistrurus site and back - saw one neonate C. scutulatus, one neonate C. atrox, and three adult C. atrox, as well as a few Bufo and Scaphiopus.

August 13 Left before 0800 hr w/ Dave and Billie and went to the slide area $\approx \frac{1}{2}$ mi E. Barfoot Lookout, where I saw the two Crotalus molossus on the 10th. Beautiful weather and lots of Sceloporus jarrovii and S. virgatus, but no snakes. After lunch stopped at Basney Tom Berlin's, where a friend of his had for me an adult Diadophis punctatus from which I palpated a small adult Hypsiglena torquata. Dave and I rode hunted in Cave Creek Canyon and E. of Portal from \approx 1830 - 1930 hr. Then went to a party at the S.W.R.S. Talked to Kim Sullivan (Utah State U.) who has three records of Crotalus pricei eating juncos at Rustler Park. Driving back, by the Cajier's place, at 2215 hr we found an adult Crotalus molossus immobile and stretched

Greene, H.
1988

August 13 out in the middle of the pavement. Never rattled
(continued) as we herded it into a bucket.

August 14 Dave, Billie, and I left early and were at
Rustler Park to look for Crotalus pricei by 0800.
We searched a hillside of scattered conifers
in an old burn area, and talus on the adjacent
slope - all in bright sun - but saw only
Sceloporus scalaris. Then went to the large
south-facing slope at Barfoot Lookout - an
enormous talus slide. At \approx 0900 hr Dave found a
huge ♂ Crotalus pricei: 530+48 mm, 108g, no
palpable food. He saw the snake because it
moved, then rattled as it went under a small
flat rock. When handled it rattled, bit
sideways, and struck at the snake hook;
repeatedly crawled for cover, but finally
coiled for photos when I covered it with my
cap.

Greene, H.
1988

September 8

Portal, Cochise Co., Arizona

Arrived here \approx 1530 hr, after a flight from Oakland to Tucson, where I picked up the Hardys' jeep. After dinner road hunted to Sistrurus area on Hwy 80, made two circuits back and forth, then back here to talk to Barney Torberlin and Tony Snell. \approx 1 mi. E. of Portal I stopped to check a juvenile Pituophis and getting back in the car saw a Micruroides crawling onto the road from mesquite grassland - not even dark yet. It squirmed and popped when restrained w/ my foot and then a grab stick. \approx 1/4 mi SW of State Line on Hwy 80 an adult Crotalus scutulatus got off the road before I could get out to catch it. Then got a small Sistrurus catenatus, immobile and stretched out - squirmed and rattled when seized w/ grab stick. Saw another juvenile Pituophis \approx 2030 hr on Portal Rd., and after leaving Barney's, another, larger Micruroides just E. of the Portal (Care Creek) Bridge - also squirmed and popped when restrained. Both of the coral snakes crawled very rapidly when first touched.

September 9

at \approx 0930 Barney and I went to check a telemetered Crotalus molossus, 2.8 mi N. of Portal on the road to Paradise. He found the snake initially in a ravine bottom w/ dense vegetation (e.g., big sycamores, alligator junipers). To the west are the main Chiricahuas rising above slopes of grass, rocks, and junipers. To the East, more open, steep, rocky country w/

Greene, H.
1988

September 8
(continued) lots of cacti, agave, yucca, and some emergent boulder outcrops and high bluffs. We tracked the snake to a rock it has been under for several days, and counted 56 clicks/60 seconds. after that we walked $\frac{1}{4}$ mile up (S.) the road and could still get a clear signal if we wore headphones. Last rain here was \approx 5 days ago - hard. Dave Hardy arrived in the afternoon and w/Barney and Tony Snell we re-checked the radio-tagged Crotalus molossus at \approx 1700 hr - 63 clicks/60 seconds. Just before that we saw an adult C. atrox on the Paradise Rd., just N. of the paved road out of Portal in mesquite. Barney and Tony caught me a Diadophis punctatus on the Paradise Rd. shortly thereafter, and Dave and I found a large ♀ Phrynosoma cornutum basking at pavement edge between their house and the Portal store. It has a substantial healed wound in front of the left hind leg. We road-hunted to the Sistrurus area and made 3 passes, but got only a Rhinocelotes lecontei on the Portal Rd. and a DOR Heterodon (stomach full) on Hwy 80.

September 10 Dave and I put down a Crotalus molossus w/ halothane that Barney and Tony caught w/in the last month on the Paradise Rd.: ♂ 1090 + 75 mm, 850 g, scar on head, 11 rattle segments - outer one incomplete, basal segment 16.5 mm, 10th Segment 16.1 mm

Greene, H.
1988

September 10

56 heartbeats/min at cloacal temperature of 26.4°C
(while under anesthesia).

Greene, H.
1988

October 11

Received the clean skull and four color slides of the carcass of an Orthogeomys undewoodi (HWG 1849) from Costa Rica, from D. K. Detourneau (asst. Prof. of Environmental Studies, UC Sta. Cug). The gopher was trapped at the junction of two tunnels at the base of a cacao tree. Sr. Geremias Arias G. told Detourneau that these gophers are active above ground at night (Sr. Arias G. worked for years as a gopher trapper for Clinton Fruit Co. at Pasita [which either is or is near the type locality of O. undewoodi], and now lives near Playa Blanca. He is the uncle of Feyner Arias G., husband of D. K. Detourneau).

October 14

Portal, Cochise Co., Arizona

arrived here \approx 1800 hr last night, after flying to Tucson and driving Billie Hardy's car here via Douglas. I wanted to see the habitat of Sistrurus catenatus along Hwy 666 (from whence HWG 1804) - it is grassland w/ areas of Yucca, and I saw at least one stream or canal and one drying pond. Farther north the grassland is heavily invaded w/ brush. Saw fresh DOR Pituophis melanoleucus on Hwy 666, Hwy 80, and the Portal Rd. This morning \approx 0900 hr Barney Torbeck and I hiked up to find the Crotalus molossus w/ new Telemetry transmitter in it. Sunny and warm, but not hot - and by noon it was partly cloudy and there was a brief shower. We found and photographed

Greene, H.
1988

October 14 (continued) the blacktail, coil in shade under a boulder and lying on rock, in thick Acacia-Opuntia-Cotilla shrub. The site is a steep slope below rimrock. Snake never moved and we didn't disturb it.

Barney gave me a pair of Thamnophis cyrtopsis he found on the road, one following the other (1850-185). From 1430-1530 hr I walked upstream from the Herk Martyr Dam parking lot, but saw only Sceloporus jarrovii and S. virgatus juveniles; I had found Crotalus and S. clarkii around the Hardys' house earlier. Met Howard Snell on the road (he was coming w/ Pat Kennedy and Jerry? [both UNM graduate students] to a meeting at the SWRS).

Took them up to check the blacktail at 1600hr. It was still coiled but a few cm from its moving site, seemingly in a better place to sun. It seemingly woke when Pat leaned close, and crawled slowly and continuously into a crevice under the rock - never rattled. By this time there were dark clouds everywhere and a slight drizzle as we descended the hill.

Rained over an inch during the night (42 mm). Dave Hardy had arrived by the time I returned from supper at the store.

October 15 This morning we surgically implanted a Telegins MOD-050 transmitter, freq. 148.4295, in a Crotalus molossus from the same slope as #1. Barney Tomberlin found this ♀ out crawling ^{at 1700hr} on October 3. She weighs 460g, transmitter 27.5g.

Greene, H.

1988

October 15
(continued)

SV 840 mm, tail 57 mm. Six rattles including base, which we painted yellow. Seemingly no problems w/ the surgery. At ≈ 1600 hr Dave Hardy and I released a large ♂ C. molossus at its capture site on Paradise Rd. (this ♂ was captured and processed last month, maintained at Dave's house, where it ate 2 Neotoma). Then we released the ♀ ("#2") at her capture site, among Opuntia, mesquite, and ocotillo. Next went up the slope and located #1, a ♂, ≈ 1 m out from his rock overhang of yesterday, amidst high grass beside an Opuntia patch. Snake was in a tight coil, rattle not showing. Didn't disturb him. Back down the slope, we found #2 in full sun on top a prickly pear clump. She didn't move or rattle as we walked gingerly around taking pictures. At ~~1620~~ 1620 hr we found a hatching Pituophis melanoleucus on the road ~~1/2~~ 1/4 mi W Portal. We returned to #2 at ≈ 1750 hr and finally found her hidden by grass in a tight coil at the base of a $\approx \frac{1}{2}$ m high agave, ≈ 2 m up slope from where we left her basking. It was getting dark fast as we descended at 1810 hr.

April 3

La Selva Biological Station, Prov. Heredia, Costa Rica

arrived here \approx 1400 hr, \approx 3 hr late because a logging truck had turned over just past el Salto falls, such that we returned to Heredia and came through Parque Nacional Braulio Carrillo. I arrived in country on the 29th of March, having left Oakland at \approx 1000 hr. Had a bumpy flight in the US, but a nice one from Miami - the pilot was José Pablo Gonzales, uncle of Carmen Rojas. Had dinner w/ Carmen Thursday and Friday nights. Went to the Instituto Clodomiro Picado on the 31st, to have lunch with Alejandro Solerzano and José María Gutiérrez. Saw a chocolate-colored Bothrops schlegeli. attended the meeting of the Board of Directors of the Organization for Tropical Studies on the 1st and 2nd. D. E. Gill (U. Maryland) told me that on \approx 7 March 1989 he and E. D. Brodie III found a small Pseudoechis poecilonotus here on the ground at \approx CES 650 m, trying to eat a nestling Dusty Antbird (Cercomacra tyrannina, "feathers in pin", 9.2 g). adult birds were screaming at the snake, and later they found it had abandoned the bird. affair took place under an Asterogyre. I had come down w/ a sinus infection the 1st, such that by the time I arrived here I was miserable. La Selva is extremely dry - the Ecological Reserve

Greene, H.
1989

April 3 (continued) swamp is dry, and everywhere open ground is deeply cracked. I'm told that except for a brief drizzle on the ~~the~~ 2nd, there has been no rain in a month or so.

April 4 I spent most of yesterday and today in bed, and possibly am getting better. Sharon Emerson (University of Utah) and I walked out the SOR and CCL to 1000 m and returned, but saw nothing. Only frogs calling at night were scattered Eleutherodactylus and several Bufo masinus that sounded as if down by the river. I saw one each Hyla elaeochroa and a small Souilisca (not bandini) on the walls of the barro in the old river station, and an adult Thecadactylus rapicaudus also. Dendrobates pumilio is everywhere to be seen and heard, despite the drought. At the Board meeting there was talk about whether increased human presence was affecting large animal sightings, and David Clark opined they are more common now, perhaps because of reduced hunting. The Clarks have had a herd of Tayassu tajacu below their house daily for a week or so, at \approx 1730 m. Yesterday and today I saw an agouti and two fennecos near the station, and at 1140 h in bright sun today an adult Sayon (Eira barbara) bounded across the new lab clearing (it had a rather bright yellow chest patch but was

Greene, H.
1988.

April 4 (continued) otherwise more or less solid black). After lunch I waded into the river below the Old River Station and searched logs up and downstream - no other (Lutra longicaudus) scats, nor could I see any from the bridge further downstream. Took photos of a swarm of yellow butterflies on a sand/gravel bar - they periodically exploded at my approach, fluttering back and forth over the river and reminding me of the famous passage in One Hundred Years of Solitude.

April 5 Alejandro Solórzano arrived ~~yesterday~~ afternoon, and w/ Sharon we walked out the CCC, CC, Sendero El Encampo, and returned by Holdridge and SOR. Hot and sunny, but it rained hard for 1-2 hours before dawn. At 0840 hr we found a ♀ Bothrops nasutus at x700 ccc, coiled to one side of trail center and facing down it - as Alejandro pointed out, well positioned to catch a foraging Ameiva festiva. It weighs 31.5g, SV 385 mm, tail 38mm. A silver-gray, almost bluish snake, actually conspicuous on the mainly red-brown soil and leaf litter. I took one photo in situ, and as I circled for a second the snake struck hard toward me, landing in an open coil - instead of the original tight one. Clearly it was alert. Tried to crawl off, but not too animated, as we hooked it into a

Greene H.

April 5
(continued)

at 0916 hr, 200 cc, a juvenile ♂ Rhadinaea decorata crawling in litter on the trail. Had a complete tail. Wriggled and exuded a foul mush when handled. In the Swamp I stepped off the boardwalk to reach for a frog or lizard and sank to my knees! After crawling out, I found a small eel (≈ 15 cm TL) that I took to be Synbranchus in the mud on my boots, and it regurgitated a worm of some sort. Saw Cebus in the swamp, and heard Alouatta on the Holdridge Trail. We passed John Arvin (Austin, Texas) w/ his group of birders in the successional plots, and shortly thereafter he found in the trail remains of a Sibon nebulata (tail and posterior adult that had been largely eaten by something). At 1035 hr., SDR 450 m, we found a Cryptophis cristatus (103+243 mm, 34 g, "perro zampopo" fide Alejandro) in litter on the trail. At our approach it hopped once or twice, a meter or so to the side and rapidly ascended a sapling ($\phi \approx 40$ mm) to $\approx 1/2$ m and froze. When seized it struggled and was periodically limp, then struggled again, but did not gape when poked. There have been two adult ♂ Iguana iguana in trees near the bridge, on the north side of the Puerto Viejo - dull colored, but healthy looking. One was basking in a tree crotch fairly

Greene, H.

1989

April 5
(continued)

close to the bridge, and responded to my presence by dropping so low as to be hard to see. At \approx 1330 hr today in bright sun I saw an adult ♀ (based on low battered spines on back), looking gaunt and very uniformly dark, basking on an emergent log on the north bank of the river.

At 1915 hr John Asrin took me to a juvenile Bothrops nasutus ($18g, \approx 270 + 42$ mm, ♂) that was stretched out in litter beside the arboretum trail. When touched w/ snake hook it made several wide, convulsive lateral snags, then paused. When picked up it writhed, ejected liquid from the cloaca, and tried to bite. A shower \approx 2100 hr.

April 6

Rained hard again this morning before dawn. Sharon Emerson and I walked out the CES and Atajo (SAT) to a rock where Mat O'Brien and I have collected otter scats before. Light rain at \approx 0900, but hot sun by the time returned. At 0850 hr at \approx SAT 200 m I spied a juvenile Bothrops asper in litter, crawling beside the boardwalk. It crawled rapidly to the underhang, and turned and bit my boot when restrained. Had a yellow tail, no food. Found three small piles of fresh Hutra longicaudus feces on the rock at the south edge of the Rio Sarapiqui.

River so high and rough we didn't try to cross it. At \approx 1100 in the Arboretum saw an adult Leptodon cayensis perch high in a canopy and, always keeping its back to us, pluck repeatedly at something.

Greene, H.
1989

April 6
(continued)

Twice the bird flew to a nearby tree, perhaps in response to our presence on a slope \approx 50 m away, and returned. When I walked down to below the tree for an unsuccessful search for bits of the prey (?) it left. At \approx 1300 hr I was taken to a yellow-tailed juvenile Bothrops asper, coiled beneath the overhang of some boardwalk steps near the repair shop and the dining hall. Snake was in a tight coil w/ head aimed out, well placed to strike an approaching lizard or heel in sandal! When I hooked it out the snake crawled rapidly w/ lateral undulation away from me, and when restrained w/ snake hook it immediately and repeatedly turned and bit. From \approx 1310-1325 hr I watched an adult ♂ Iguana iguana just below the north end of the bridge crawl across an expanse of leafy vegetation and eating almost continuously. I could clearly see leaves contacted by the tongue, and some of the leaves were several square cm and easily ingested. Also saw a gaunt ♀ high in a tree, in shade. Talked w/ Ruth Tiffer, who works for Cathy Pringle on the streams project (31-03-93, Apdo. 346, Paras, C.R.) and who knows a lot about local crustaceans. She told me that there are large freshwater crabs here (like I saw the Lutra eat below the bridge), that several species of local shrimp belong to the genus Macrobrachium, and that those in the Lutra seats I collected this morning belong

Greene, H.
1989

April 6
(continued)

to the genus Alyga. She said there can be marked variation in abundance and species composition of spring assemblages by stream, season, and even daily (the last because of rainfall effects). From $\approx 1430 - 1700$ walked out the CCC and 50 R to release the Bolitoglossa nasuta and Crotaphopeltis from yesterday (?), then stopped at the waterfall. Most of the time a fairly heavy rain fell, but before dusk there was scattered sunlight. Jack Ewel (U. Florida) also saw a juvenile B. asper today. Began raining after dinner and continued into the night. From $\approx 2000 - 2200$ hr Sharon and I walked to ≈ 650 CES and back, and through the Ecological Reserve Swamp. More scattered frogs calling than on previous night, and we saw a Norops limifrons asleep on a leaf, a Hyla leucosticta perched on a leaf, and found an Imantodes cenchoa crawling in litter beside the sidewalk, just into forest from the laboratory clearing (2215 hr, $480 + 315$ mm, slight odor when handled).

Still no water in swamp, nor frogs seen.

April 7 Rained all morning. At noon Guillermo brought me a very fresh scat of Felis onca or F. concolor, from junction of the CCC and 550. He and Joel saw a Tucupitris semiplumbea, eating, or rather holding a stilllive Ternanou chick. Left La Selva at 1330 hr, to leave San Jose for the U. S. early on the 9th.

Greene, H.
1989

May 5

Briones Regional Park, Contra Costa Co., California

Ted a Zoology 107 field trip here, from 0800 - 1200, on a beautiful warm, sunny day. Water in all four lagoons (we came in from the Alhambra Valley Rd. side), but three of them heavily trashed by cattle. Saw 3 Pituophis melanoleucus (all adults above ground in open grassland), 1 juvenile Crotalus cerberus, 1 juvenile Thamnophis elegans, and 1 adult T. couchii (regurgitated Gasterosteus). Also heard Hyla regilla, caught juvenile Rana aurora, saw numerous Sceloporus occidentalis, and counted 16 Clemmys marmorata basking in the fenced Sinesich Lagoon.

May 6

Repeat of yesterday's trip: 1 Pituophis melanoleucus (same sub-adult animal seen yesterday), 2 Crotalus cerberus (1 ad., 1 juvenile), 4 Thamnophis couchii (1 ad ♀ from Upper Sinesich regurgitated a Tanicha), plus lizards and turtles and frogs.

June 4

Portal, Chiricahua Mtns., Cochise Co., Arizona

Arrived here ≈ 1330 hr w/ Claudia Duke, having left Berkeley on the 1st. Visited Howard Jawter in Tucson, who said he has seen Crotalus atrox, C. tigris, and Phyllorhynchus browni on the roads lately although there has been no rain. I visually located the adult ♂ Crotalus molossus (we have been radiotracking since last August) high on the slope where it's been all winter. The snake is in a hole within a crevice, under a flag

Greene, H.

1989

June 4
(continued)

That indicates David Hardy found it here on May 6th of this year. The hole is only a few cm in diameter, and all I could see was the side of a body segment w/ the head resting on it and facing directly out. The snake's colors seem dull to me, but the light was poor. Is it waiting to shed, waiting for rain (not due for another month or more), or waiting for a Neotoma to choose that hole for a nest? The last doesn't seem likely because the snake seems ill positioned to strike. I stabbed my knee on an agave or some other plant coming down the slope. Beginning \approx 1930 hrs, I rode hunted until \approx 2115 hr - up Cave Creek Canyon to SWRS, down to Portal and out to Hwy 80 via StateLine Rd. Drove to \approx 22 mi SW of StateLine Rd. to the area where I collected Sistrurus catenatus last year and made two circuits of the Bernardino Valley. Saw no snakes all evening, nor did I see any lizards going up to see the blacktail.

June 5

Drove up to SWRS and back at \approx 0930, w/ a sidetrip to South Fork - saw only birds and a squirrel. Creeks dry in lower canyon, but there is still a low water pool below the South Fork picnic area as well as at least one bridge on the way in. From \approx 1630 - 1730 hr I explored at the base of the slope on the W side of the dry bed of South Fork, $\approx \frac{1}{2}$ mile from the turnoff. Very dry, although there were insects under some rocks. Saw a few active juvenile and adult Sceloporus

$$\frac{e^{\alpha}}{n} \geq nQ_{\alpha,\beta}^{(m)}$$

Greene, H.
1989

June 5 (continued) jasoni. When I turned a flat rock \approx 40 cm in greatest width, a juvenile Egernia kingii dashed \approx 50 cm to the cover of a roller oak log. The lizard had a well-banded, unregenerated tail, and I could clearly see sinuous waves in the trunk and tail as it rapidly scurried away. It initially froze upon reaching the cover of the log, as a small portion of the tail remained visible until I reached for it. I tore up the log and litter, but the latter was thick and I failed to find the lizard. Drove up to SWRS before returning to the Hardy's house, but still no snakes. From \approx 1920 - 2100 hr I made two circuits on the road, from Portal to SWRS, back to State Line, and then to Portal. Saw six white-tailed deer, but the only keep was a fairly fresh DOR Phrynosoma modestum at 1950 hr, \approx 3 mi E. of Portal. Only a sliver of a moon, which was at times obscured by clouds, so it's very dark.

June 6 Checked the telemetered Crotalus molossus, found him at 1705 hr - the crevice is in shade from the rocks it is in and two large Opuntia patches above and west of it. I photographed the snake, which lie in an elliptical open coil, w/ body extending well out of the crack. The head was easily visible but back w/in the hole. No tongue flicks or other sign of the snake sensing me, and I was at pains to not disturb it. Probably could have caught it, but I want

Greene, H.
1989

June 6, To check its morning behavior. From ~1940-2150 hr
(continued) I drove from Portal to the sithurus site and saw no snakes. Basney, Tom Berlin and Tony Snell picked up a Micruroides euryanthon (sc: Leptotyphlops, swallowed head-first) during that period, hit by a car in front of them. Two nights earlier they saw DOR Pituophis and Crotalus molossus on the Portal Rd.

June 7 With Basney and Tony, checked the Crotalus molossus at 0850 hr, when the slope has been in full sun for several (≥ 3) hours. We could only see the edge of a coil, deep in the hole. Then Tony took me high above on the steeper rock face to the winter sites.

~~Two~~ Two holes the snake used are now plugged w/ dirt and litter — if that is typical, a snake using this slope can not depend on a particular hole — but of course there are many holes. In fact, our snake used several over the course of winter, some of them more than once on different occasions. After lunch

Claudia and I drove up to the slide, just before the turnout to Barfoot, where I've caught Crotalus molossus and C. pricei in the past. Everything is exceptionally dry and the soil among talus everywhere exposed — at first I wondered if the Forest Service had run some huge machine over the area! Saw only a few Sceloporus jarrovii, adults and hatchlings.

Went to Barfoot campground (now filled with Boy Scouts) for photos of the slide, and also saw several S. jarrovii there. Drove back via E. Turkey

Greene, H.
1989

June 7 (continued) Creek Canyon (which has water) and Paradise. At 1715 hr I located the telemetered Crotalus molossus still in his hole this time w/only the head showing - facing directly out and largely filling the hole. At 1726 hr as I came down from that site, and only a few 10s of m below it, a Salvadora grahamiae dashed a meter or so then froze stretched out near a bush, whereupon I grabbed it w/ Pilsthorn Tongs. Site was already in shade of the bluff. From 1945-2100 hr I repeatedly drove the first 2-3 mi E. of Portal, but saw nothing.

June 8 Antelope Pass, Hidalgo Co., New Mexico
Visited an array of can trap grids extending from W. side of this pass to E., run by Barney Torberlin and Tony Snell for New Mexico Fish and Game Dept. This morning, at the ~~western~~-most site, we saw in the cans Cnemidophorus sonorae, C. tigris, Cophosaurus texanus, Phrynosoma modestum, Uta stansburiana, and a Heloderma suspectum! I found the latter in a can near mesquite and other dense vegetation, ≥ 2 m from the edge of a dry wash. It was a very young one, very pale and w/ a distinct umbilical scar ($134+53$ mm, 30.4 g.). Very feisty - squirmed, gaped, and readily bit a plastic bag. At the ~~western~~-most site (Town of Animas visible in the distance) we saw an adult Phrynosoma

Greene, H.
1989

June 8
(continued)

modestum sun at our feet in open scrub. The animal made several short runs ($\approx 1\text{ m}$), and each time upon stopping wagged its tail back and forth several ($\approx 3-6$) times. The plane of movement was largely lateral, but at times the distal $\approx \frac{1}{4}-\frac{1}{3}$ was slightly deviated.

Portal, Chiricahua Mts., Cochise Co., Arizona
as we pulled into the Hardy's driveway I saw an adult ♀ Pituophis melanoleucus slowly crawling in full sun at 1116 hrs. Only response to being picked up was attempt to crawl away. Freshly shed (bright colors and one small piece of old skin on her side), neither skinning nor fat. Palped a small rodent (sawed) and released the snake. At 1644 hr I found the Lebercheck Crotalus molossus deep in its crack/hole, only a loop of its body visible by flashlight. From $\approx 1900-2015$ hr Claudia and I repeatedly ~~had~~ hunted the first ≈ 2 miles east of Portal, but saw no snakes.

June 9

at 0805 hr I saw an adult Pituophis melanoleucus escape into grass and mesquite $\approx 1/2$ mi w. Portal. San Bernardino Valley, Cochise Co., Arizona
arrived here ≈ 1000 hrs w/ Barney Torberlin and Tony Snell, to scout the area for future studies on Sistrurus catenatus. First we visited the Robert Krenz Ranch, which is a few miles NW of Hwy 80 on Rucker Canyon Road. We were met

Greene, H.
1989

June 9
(continued)

by Bob Krentz (age 64) and his son, Robert. The former in cowboy hat, the latter with strange blue, indirect eyes and dressed like a mechanic. They were stand-offish at first - referred to my Toyota truck as a "rice rocket" and wanted to know why I didn't "help out the goddamned economy by buying a Chevy!" They've had bad experiences w/ scientists in the past, particularly Peter Wassen and his crew from Purdue, and are clearly skeptical, but also were soon genuinely hospitable in an undemonstrative way. Told us we're welcome anytime, offered me a key to the gate, etc. We talked to them \approx 30 minutes about drug runners, federal bureaucrats, etc. - all of which they view as threats. We also met the younger son, Phil, whom Robert earlier referred to as "the ready one likely to give you trouble." Bob Krentz enlightened me as to where the "Chisicahua" of older maps was - precisely at the junction of (now) Rucker Canyon Rd. and Hwy 80; it was a railroad "siding" and encompassed a small community, but \approx the end of World War II the railroad moved its workers to Douglas and the place disappeared. This makes sense in terms of that old specimen of Sistrurus catenatus from "Chisicahua."

Greene, H.
1989

June 9 (continued) Driving out from the ranch, we stopped to catch a large adult ♂ Holbrookia maculata ~100 m from the junction w/ Hwy 80. It was sunning on a rock ~1/100 hr, on open red soil near scattered grasses — as we approach to noose the lizard it ran ~1 m and frozen w/ its head in a grass clump. It struggled and gaped to bite when handled. Walked around to look for others, but saw only Cnemidophorus uniparens. Next pulled in at a ranch gate a few miles further SW — just over the hill from the long sweeping S-curve where I caught Sistrurus last year. Walked up to an abandoned cinder mine, from which I took photos SW, E, and NE of the valley. Saw two small adult (bright green) Crotaphytus collaris, one under fir and the other under an old firkin. Tony saw a Urosaurus. There is a raven nest on some sort of rusty, protruding mine equipment, causing us to speculate that one could have poached raven eggs after a lightning storm. There is at least one barn owl nest ^{site} ~~sight~~ in a hole in the hill at the mine, ~~the~~ with a pile of pellets and rodent bones below it. The soil here is a rich red-brown, about like the coat of some Herefords or perhaps a Santa Gertrudis. It is very dry now, the grass light yellow-brown.

Greene, H.
1989

June 9 (continued) The only likely shelters for Sistrurus I saw appeared to be kangaroo rat burrows, which at this place are clustered into mounds. I noticed a few wallow-like depressions, roughly circular and a few meters across w/ different vegetation, that Barrey says fill w/ water during the monsoon. There is a fair amount of tin and boards around the mine, but all such that underneath would be far too hot for a small rattler. Digging out we saw that there is an obvious marshy area at the valley's low point, in the middle of the S-curve — precisely where one most frequently finds Sistrurus and Thamnophis marcianus. My bet is the massasgas stay there through the cold and dry part of the year, and move outward up the valley slopes of grassland during the monsoons. Barrey and Tony had previously found an adult Crotalus atrox and Pituophis under a rusty abandoned truck at the mine, and many C. scutulatus in the grassland below — either lying out or in the mouths of k-rat burrows.

Postal, Chiricahua Mts., Cochise Co., Arizona
at 1630 hr I could see the side of the body of the telemetered Crotalus molossus, against the entrance of the hole he has been in all week. Hot & sunny, tho even now the hole is in shade. Claudia and I

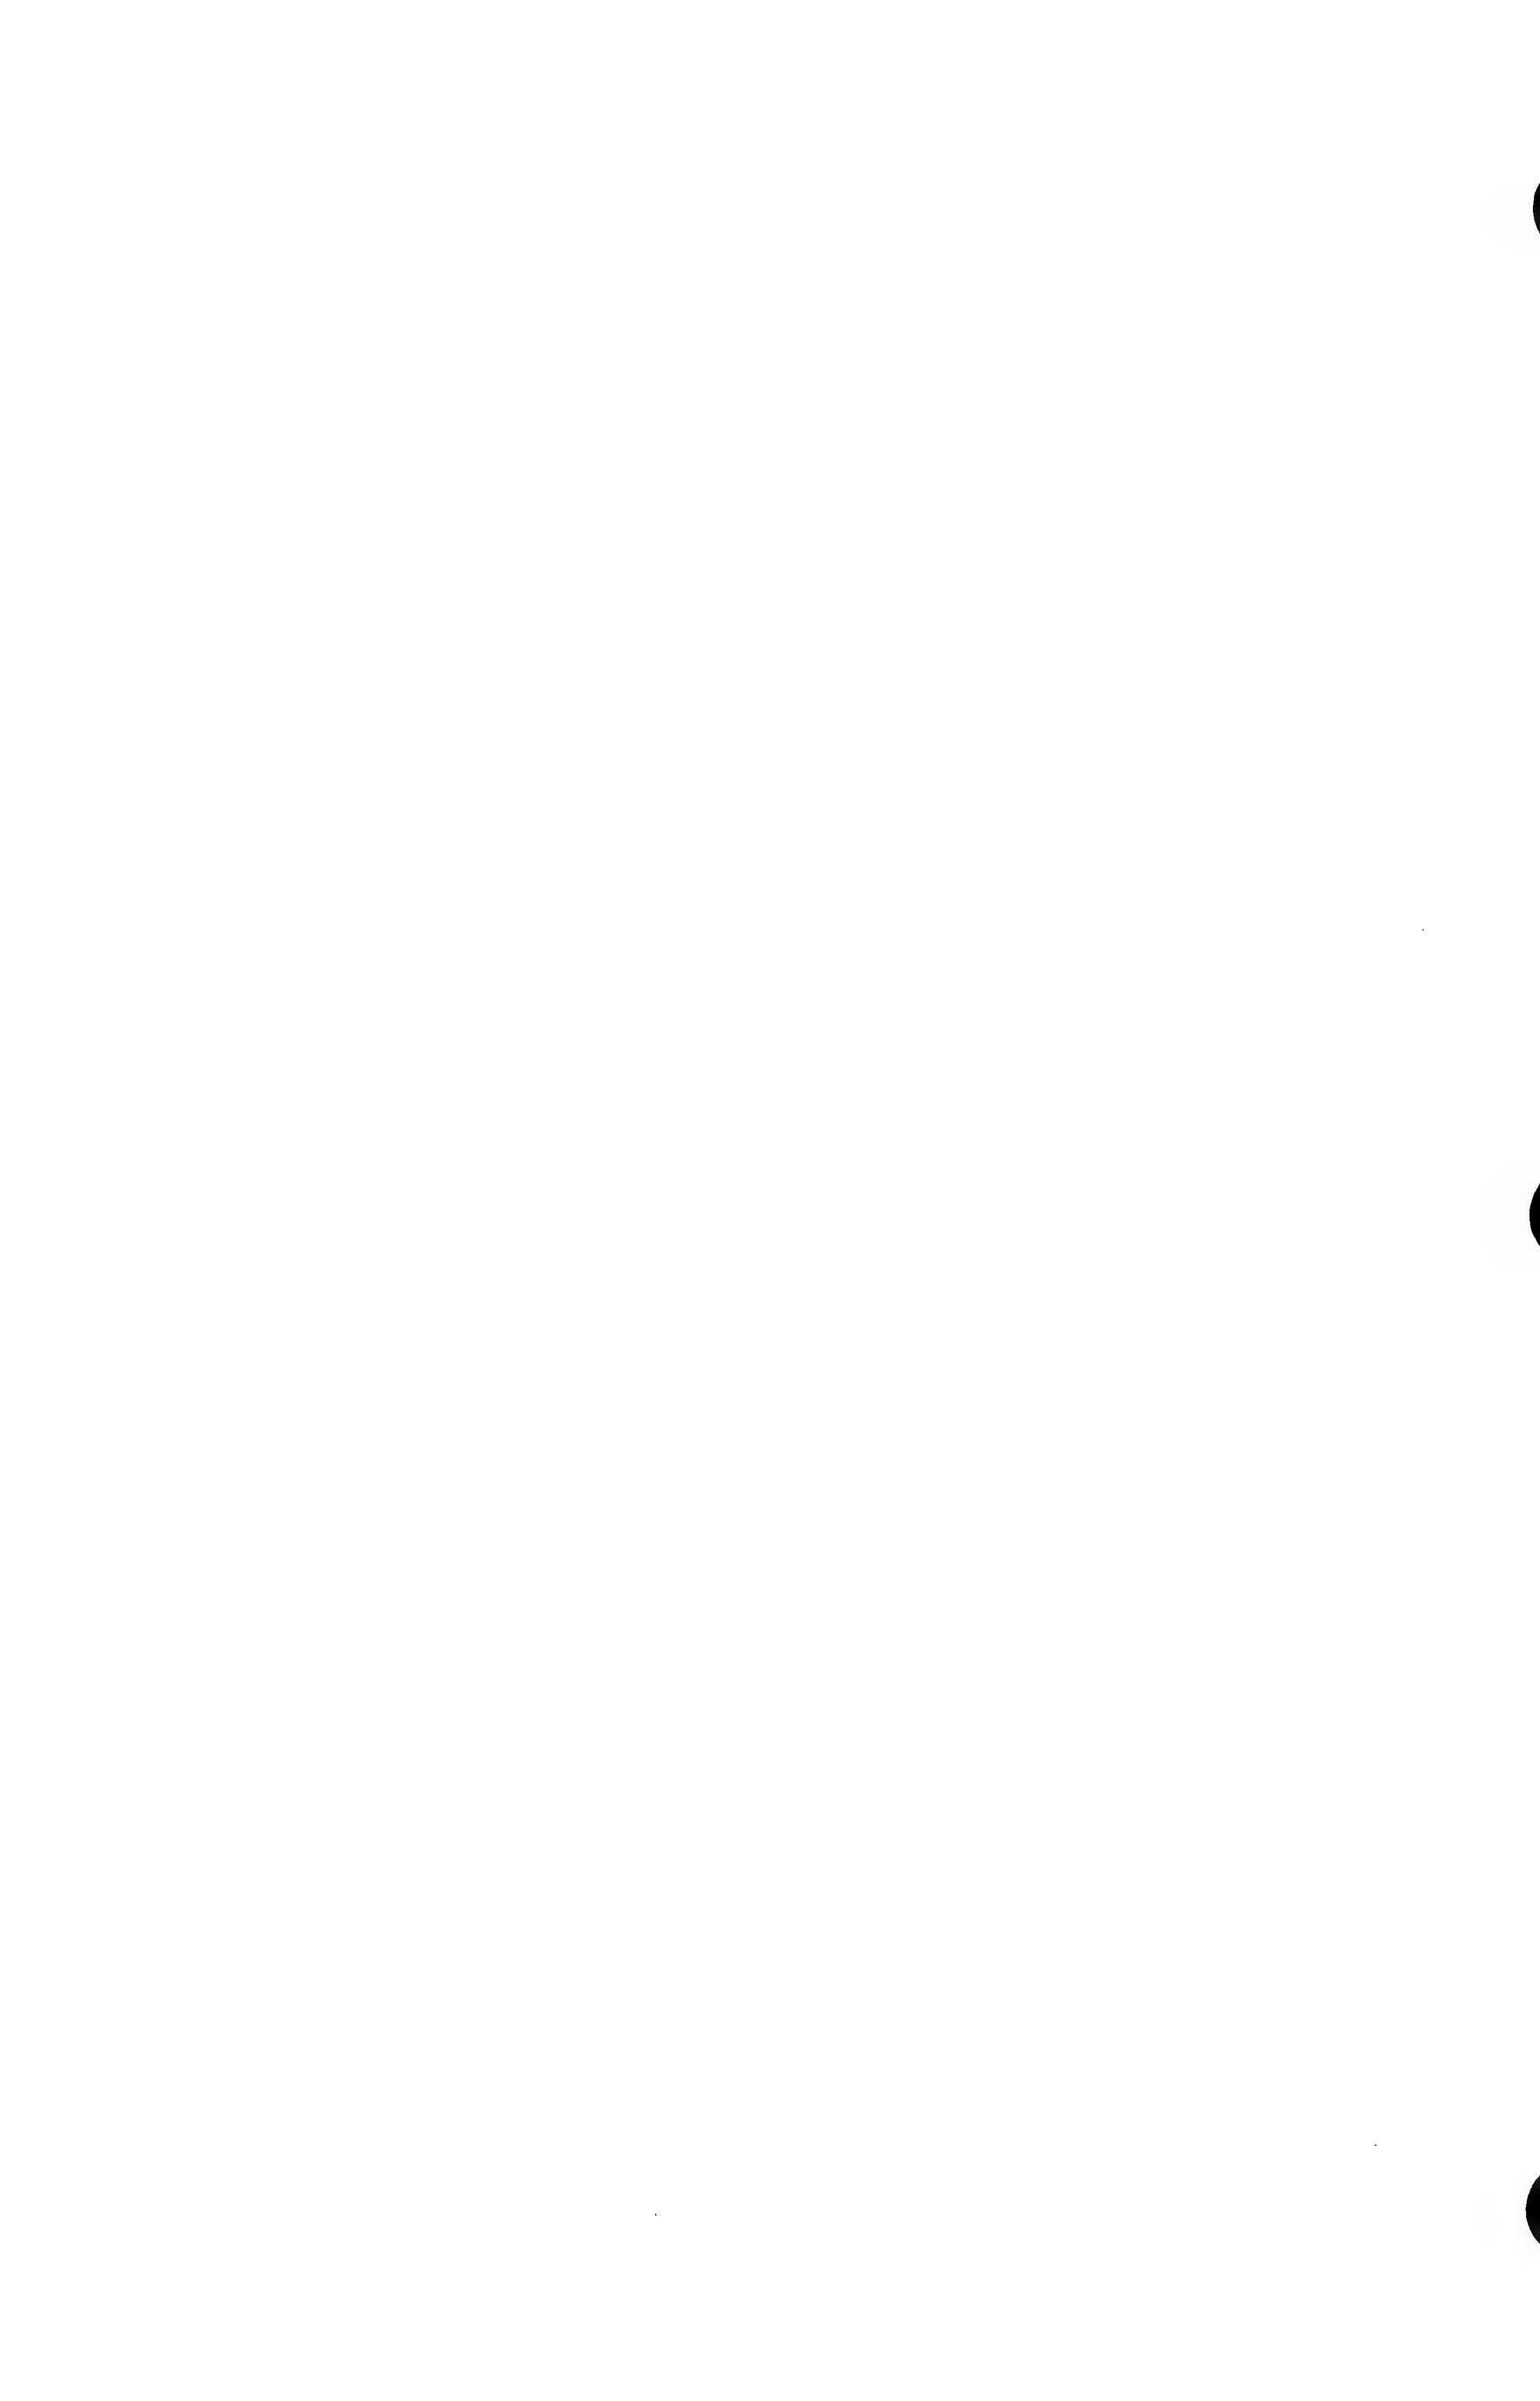

Greene, H.
1989

June 9 went to SWRS for dinner from \approx 1730 - 2230 hrs., but
(continued) saw nothing on the road. George Q. Middendorf
(Howard University) told me that he saw (in a past
year) an adult Elaeophis in South Fork Canyon
climb an agave and eat some nestling birds.

June 10 Spent the morning preserving snakes Basney gave me.
From \approx 1500 - 1800 hr Claudia and I hiked the trail
to Ashe Springs and Herb Martyr Dam, but saw only a
few Sceloporus janovi. After dinner at the Portal Store we
drove to the Sistrurus site and made three passes over the
3.5 mile stretch between Rucker Canyon Rd. and the ranch
gate to the cinder mine. On the way out we got a DOR
Phrynosoma cornutum and a DOR Pituophis.

June 11

Greene, H.
1989

July 3

San José, San José Province, Costa Rica

Arrived here on LACSA at \approx 1530 hr, noticed again how their pilots make more exciting landings than gringos — we made a complete, tight, low circle and came in for a perfect landing. Spent this morning working on Sceloporus atrocinctus and Tantilla annulata in Jay Savage's collection (spent last night w/ he and Becky — promised to send her Darla Billiard's book about snow leopards. Alejandro Solozano picked me up; told him I really want a live Sceloporus and by coincidence he has one — a big pretty ♀ from near here!

I weighed it after \approx 1 hr of rehydration and fresh defecation. ^(see July 6) I detected no response to handling except rapid undulation. What a nice surprise! I'd call the light "rings" off-white or creamy, slightly gray; the middorsal stripe is bright deep salmon pink — and suddenly it occurs to me that this color pattern (which I have been considering unique) occurs in some Sonora semiannulata. Savitzky thinks Tantilla and Sonora are related, and since Sceloporus looks like a Tantilla w/ a tiny loral perhaps it and Sonora share some homologous aspect of color pattern. Also visited Alejandro's "Serpentario," which is downtown — an excellent exhibition and gallery of Fogden prints.

Greene, H.
1989

July 4

Shopped in the morning, then joined Alejandro Solerzano and José María Gutiérrez (Director of the Instituto Clodomiro Picado) for lunch. Spent the afternoon looking at snakes at I.C.P. and Serpentario.

July 5

Estación Biológica La Selva, Heredia Prov., Costa Rica
Arrived here after an uneventful trip, ≈ 1030 hr, in a light drizzle. Cloudy all afternoon. ≈ 2000 hr I walked out the CES to ≈ 200 m, then back through the Cantarana swamp - no snakes. Water almost up to the boardwalks (there was reportedly a tremendous storm last night), and scattered frogs (Hyla loguax and others) calling. Saw a small Bufo marinus (≈ 80 mm) on sidewalk in the lab clearing.

July 6

at 0559 hr I saw a lutra, freshly wet, ~~dry~~ off a log near the N. bank of the Río Puerto Viejo, below the La Selva bridge. It resurfaced a few seconds later ≈ 50 - 60 m downstream, then dove again. Photographed the live Scolecosphis - only response to handling is violent thrashing, often w/ body extended semi-rigid. Examined the feces - ^(see also July 14, 1989) scattered arthropod parts, but not much for size of the initial feces. Most of it was unidentifiable small debris. The parts were yellow-brown, and at least three looked like segments of Scolopendra. From ≈ 0900 - 1000 hr I walked around the area ≈ 500 m CES, near Don Penny's Leitkay's tree, where several Lachesis have been seen. Then out to the Arboretum, where

July 6 (continued) at 1015 hr I spotted a big ♂ Pseudoechis poecilonotus (800g, 1379+537mm) lying in grass in a patch of dappled sun. It was immobile and easily mistaken for a branch. Didn't move until I touched it, then instantly inflated most of the body, gaped widely, and bit my forearm — and wouldn't release easily! Some odor — not strong or especially disagreeable — was evident by the time I bagged it. Several Iguana and Rhinoclemys visible from the bridge at noon. Thunderstorms upslope in the afternoon and sporadic rain in the evening. Went to Carlsbadna Swamp twice and out CES to 300 m — scattered frogs calling at x2040 hr David De Santi (formerly Point Reyes Bird Observatory) encountered a \approx 1 m Bothrops asper crawling on the sidewalk at the River Station. It struck "at his light" and went under a low wooden box in nearby grass, where I found it coiled and alert (head up on coil). A few seconds after I lifted the box it crawled rapidly \approx 1 m and froze w/ body extended and head up; whereupon I lifted it on a hook into the can. Snake struck repeatedly, \approx reaching the can's top edge (x45 cm from bottom). (125g, 735+100 mm)

July 7 Rained hard during the night, tailing off during breakfast. From x0900-10:30 I walked out to Holdridge \approx 600' and back via Carlsbadna Swamp, in a light drizzle. As I returned to the lab

Greene, H.
1989

July 7
(continued)

Taura (cleaning woman) showed me a Corallus annulatus coiled tightly between a rafter and the eave of the porch in front of the main AC laboratory. When I hooked it down the snake tried to crawl away, fairly rapidly for a boid, but when I swung it between my legs it bit my pants and continued trying to bite while I restrained it behind the head. Snake is very chocolate brown, in contrast to the two brick red juveniles and large pale sandy adult I've seen previously. The boa (240g, 1005+195, ♂?) was in a compact, circular coil w/ head over the edge, facing out from the building — thus in a more or less typical Corallus posture, except in an approximately horizontal plane perhaps caused by its size relative to the beam on which it was resting. David and Billie Hardy arrived before noon. After dinner, \approx 2000-2200, Dave and I walked to CES 700 and back, down to the Sura Trail, and over to the Cartarana boardwalks. At \approx 2050h we located a young adult Hadesis muta at Sura 175 m, coiled alert on the S side of the trail — presumably a snake Nancy Greig saw recently at \approx 150 m on this trail. The snake was in the open cleared border but near forest edge, facing the boardwalks and I think w/in striking distance. It was alert — tongue flicked and oriented w/ head when I walked nearby or set off a camera flash. I was able to hook it into a garbage can on first try w/out difficulty.

Greene, H.
1989

July 7
(continued)

although the snake maintained a striking coil and was orienting to me as I lowered it into the can. $\approx 2140\text{ hr}$ Dave spotted a large adult Leptophis ahaetulla asleep $\approx 3\text{ m}$ above the water in a small tree, perhaps 4-6 m from the boardwalk. The snake was in a loose coil, head oriented into the tree. Soon thereafter, near the eastern boundary of the swamp, we found a very large adult Hoplocephala septentrionalis evidently hunting frogs. The snake was $\approx 4\text{ m}$ above the water in a slender, sparsely vegetated tree or bush. It was descending a branch, almost vertical and not much larger in diameter than the snake. The movements were slow, the head kept close to the branch surface, and there were numerous short lateral movements. At one point it appeared to be pressing or poking at a patch of moss. At first I could see only the venter of this snake and thought it was Dipsas insomnis—but then realized the body was a little too heavy and the belly more yellow or even slightly rose, and eventually got a good look through binoculars at the head and dorsal pattern. Frogs seen include Hyla glaucochroa and 2 Agalychnis saltator, and others were calling. When I checked again at 2220 hr the Hoplocephala was still searching slowly, but ascending and $\approx 1\text{--}1.5\text{ m}$ higher in the tree.

Greene, H.
1989

July 8

Cool and cloudy, then sun after dawn. At 0615 hr the Leptophis ahaetulla we saw last night in the swamp was not to be seen. Substantial rain starting by \approx 8:30 - 0900, so we worked in the lab. Yesterday one of Doug Zeng's Earthwatch people perfectly described to me the color pattern of Pliocercus euryzonus (actually just placed in Urotheca by Savage & Crother) and said he saw 2 on July 6, after dark at either end of the Cantarana swamp. From \approx 1430 - 1600 hr Dave Hardy and I walked out the CES to LOC 450m, where Robert Marquis (U. Missouri - St. Louis) saw a large Bothrops nasatus this AM - it had been on the path, then crawled onto an old fallen log. We failed to find it, but on the way out Dave spotted a B. nasatus that I walked over. It was a little snake (201+20 mm, 8.3g) and coiled in dead center of the boardwalk, next to a leaf, and perpendicular to the trail. The snake was in a tight coil w/ head up on outer coil & neck in S; stomach empty. I was able to lift it into a bag w/ forceps w/out disturbing it, but when I tubed the snake for palpation it squirmed about its long axis, ejected a considerable quantity of clear liquid from its cloaca, and bit at the tube sides repeatedly. Dave Hardy and I walked through the Cantarana Swamp and out to CCC \approx 700m from \approx 2030-2200 hr, after I gave a talk to the OTS agroecology course. On the

Greene, H.
1989

July 8 (continued) way out, \approx 2100 hr, we saw an adult *Leptodeira* *inornata* lying \approx 1.6 m above wet ground on the W. edge of the swamp on palm leaves. A few minutes later we saw a large adult *Leptodeira septentrionalis* crawling slowly at the same height in the same tree as last night. On the way back couldn't see the *Leptodeira*, but checked the *Leptodeira inornata* ($690 + 155$ mm, 32 g) - a gravid ♀ from which I palpated a freshly head-fist ingested *Hyla eleutherodactyla*, gravid ♀ ($5 - V 31$ mm, head-width 11 mm, 2.4 g).

July 9 San José, San José Prov., Costa Rica
arrived here \approx 1100 hr, w/ a room at the Hotel Johnson, after a bus ride via Braulio Carrillo National Park. Just W. of Rio Frio the bridge is out, so everyone exited one bus and trotted across an old foot bridge to catch another in the town. w/ Alejandro Solozano, met Ardell Mitchell (Dallas Zoo) at the airport.

July 10 La Selva Biological Station, Heredia Prov., Costa Rica
arrived here \approx 1100 hr w/ Ardell on the OTS car. Dave Hardy had gone out last night but got nothing. After lunch we anesthetized the young ♀ *Lachesis muta* caught a few days ago on the Sura Trail. $1235 + 120$ mm, 9.95 g. Clipped right half of snake's 3rd vertebral anterior to anal plate. She has longitudinal

Greene, H.
1989

July 10 (continued) midventral scars on #'s 24, 31, 65, ad 110-113 starting from the oval plate (as "O"). No evidence of external injuries. We implanted a Telonics transmitter (27.8g), 151.270 mhz. No apparent problems. On the 8th she defecated a large quantity of spinose rodent fur. We watched her for an hour or so after, during which she was slowly recovering responses, and at one time a gentle nudge provoked tail elevation and slight curving - a response I saw in an adult once after handling. Also, as she was anesthetized the snake mashed repeatedly in a manner that people were hit several feet away. After dinner Dave and Ardell and I walked out the CES to 700m and to the Cantarana Swamp via Sendero Sura, but saw nothing save frogs.

July 11 at 0800 we released the Hadesis muta at the capture site and left her immobile and in an alert coil; later Billie Hardy reported that w/in an hour the snake was not to be seen. Dave and Ardell and I walked around the Zoo Trail, then out to Holdridge x 150m in an unsuccessful attempt to find a "very fat" Bothrops nasutus that Jack Ewell saw there yesterday. At x 0830 hr a Norops capito hopped several times across our path, and expanded its dewlap when Dave seized it (ccc 50). At lunch Rocio Lopez brought me an injured juvenile Ninia maculata.

Greene, H.
1989

July 11 (continued) That a visitor found on a cement path in the lab clearing at \approx 1200 hr moon ($122+31$ mm, 1.2g). Just before lunch Dave and Ardell and I used a receiver to locate the Lachesis muta, now coiled under a small plant ^(a Pepper) and a few meters in shade from where we released her. I walked very near before locating her visually, yet she simply remained immobile w/ head up. At 1310 hr Ardell found an adult Scaphiodontophis venustissimus (415+
125+? mm, 43.5g, ♀?) crawling across a cement path at the edge of the lab clearing, in ^{forest} shade. Response to handling was rapid erratic crawling, w/ jerking of the incomplete tail. No musk or biting. At 2145 hr we found the Lachesis muta still under the plant, after we had walked out to CES 700 m - caught only an Eleutherodactylus fitzingerii (8g) in litter on the Sendero Sera.

July 12 Rained all night. at 0604 hr found the Lachesis muta under the plant, and again at \approx 1045 hr. In between we walked \approx 200 m out into the forest at CES 500 looking unsuccessfully ~~for~~ ^{for} Lachesis. At 1310 hr a workman showed me a small, brightly colored micurus nigriceps under a tractor wheel (4.0g, 265+25). W/ Dave and Ardell, walked out CCC to Carrizo Arbol, via El Scampo to Sendero Holdridge and back in. Found a cat scat, evidently containing Tayassu, at CCC 220. at \approx 1930 hr Billie Hardy

Greene, H.
1989

July 12 (Continued) found a Ninia sebae on a sidewalk in the lab clearing (8.3g, 255+91 mm). From 12030-1300 hr we walked around the Cantasara swamp. Found a large Isthmochelys euryzona (437+306, 55g) "nosing" in leaf litter beneath palms a few (\approx 20) m from the water edge. It thrashed wildly and repeatedly coiled its tail in tight loops on my hand. I found a Leptophis ahaetulla (800+530 mm, ♀, 74g) asleep on leaves at the tip of a sapling \approx 5 m above ground and w/in 10 m of the swamp water edge. She regurgitated 3 Hyla elaeochroa: 2.8g, 38mm, +f, ♀; 1.8g, 36mm, +f, ♂; 1.2g, 30mm, hf, ♂. Then an Leptophis nebulosus (460+295 mm, 13.5g) asleep on a palm, stretched out w/ some loose curves. Squirmed, musked when seized; later gaped in bay. Regurgitated a Hyla elaeochroa (29mm ♂, 1.6g, hf).

July 13 Rained during the night, and lightly during the morning. Someone (Rob & Ron) brought in a little Bothrops nasutus (216+21 mm, 9g) from leaf litter near the lab clearing. From 1330-1500 I walked around CCH & CCC - sunny - but saw only 1 Eleutherodactylus, at 1500 hr Ardell was shown an Leptophis depressirostris that had been found swallowing a frog on sidewalk in the lab clearing (607+371, 63g) - from which I palped an Eleutherodactylus (SV 29, 2.1g) that had been

Greene, H.
1989

July 14

Some rain during the night and on the way to breakfast - a cool, dreary morning. Found the Leptophis ahaetulla from the swamp dead, so picked it. Also the Scolecophis from Pavas, which had an infected eye and a couple of water blisters. It had defecated again and segments and one leg w/ "claw" were clearly visible ^{1 (as centipede)} under a scope. Forgot to mention earlier ① a few nights ago Dare and I saw an armadillo (Dasyproctus novemcinctus) on the CCC (same general area where Feyner Godivas dies and I saw the injured one on a previous trip); ② last night Ardell saw a large Didelphis marsupialis cross ahead of us on the CES; and ③ a few nights ago on the CES I spotted an adult Greater Tinamou roosting on a horizontal branch \approx 8-10 m above the ground and \approx 1 m out from the tree trunk. Weights and measurements of two live Eleutherodactylus: ① E. fitzingerii, SV 47 mm, 8 g; ② E. transversi, SV 21 mm, 1.2 g. From \approx 1430-1700 hr. Ardell and I walked through the arboretum and out the Sendero Sura to LOC, then to Sendero Atajo out to the Rio Sarapiquí, and back to the station via CES. Hot and humid. At 1450 hr we found an adult ♀ Bothrops mosaueri at Sendero Sura 905 m - she appeared extremely thin and evidently nearly parturient, so we only nudged her off the trail rather than add stress by handling her. Picked up cat scats at Sura 690m and Atajo 550m, then 1 old and 2

Greene, H.
1989

July 14 (continued) fresh otter (utra longicaudus) scats on the traditional otter rock on the Rio Sarapiguí, near the end of the Sendero Atajo. Ardell spotted an otter in the broad area of riffles just down stream, and we watched it for ~10 minutes. Throughout that time the otter was always underwater - presumably hunting - or upright out of the water to shoulder level and eating. Dives seem to last 5-15 seconds, and about that same time was spent eating. Sometimes a food item was held in a paw briefly, but most pre-swallowing involved only chewing w/ the mouth visibly open. All prey appeared to be crustaceans, and once an item flipped or slipped out and through the air into the water. I was struck by how easily visible the otter was; it always faced into the late afternoon sun to my back, and appeared very light colored around the chest and chin.

After dinner Dane and Billie went out the CE 5 to 700 m but saw only a probable Bassanicyon gabbi. Ardell, Ana Gonz, and I went through the Cartasana to CCC 700 m. As we returned Ardell spotted an adult, white and black banded Urotheca (Pleioscincus) lusyzae immobile beside the trail. It began violent crawling at his approach, then thrashing as he pinioned it w/ his hand. This was at 2058 hr. When I tried to palp the snake at 2130 hr in the

Greene, H.
1989

July 14
(continued)

lab, it squirmed violently, coiled its incomplete but well healed tail around my fingers, and snapped off a segment. There was considerable bleeding from the proximal tail segment (remaining on the snake), and \approx 15-20 minutes later I was able to measure ≥ 1 cc of blood in the plastic bag in which I immediately placed the snake. The tail flipped from my hand to the floor and thrashed rapidly and sinuously, and I started a stopwatch w/in 1-2 seconds of the break. Its movements were very regular and resulted in alternate flexion and coiling into a tight circle; the proximal end simply arched back and forth, but the distal end always mashed very symmetrical S-curves. So, a series for the proximal end looked like: 7151715. A series for the distal end looked like this: 02, 16, 05. After 5 minutes and 35 seconds the flexions had slowed noticeably, and for the first time flipped so the ventral surface was appermot. At 8 minutes and 55 seconds the flexions began to be interrupted by brief pauses. At 9 minutes and 38 seconds, 11:29, 12:30 13:44 movements only resumed after I pinched the tail. At 13 minutes and 59 seconds there was no evokable movement. The shed tail piece was 155 mm long, and weighed 5.4 g. The remainder of the snake wt. 43g; 425 + 82 mm. at \approx 2230h I found the

Greene, H.
1989

July 14 (continued) Hachisus muta at Sura 165m sleeping - head down as before. Checked the Contarana, but found no further snakes.

July 15 Cool and overcast all morning - took a nap. After lunch Ardell saw a Nasua chase and almost catch (he scared it) an adult ♀ Basiliscus plumifrons in the lab clearing. From $\approx 1430-1630$ I took Richard Foster, Chaves? (his nephew), and Carol Farsetti (all from Partridge films - working on a snake picture) around the CCC-CCL loop, but we saw nothing. After dinner found the Hachisus muta as it has been. Dave, Ardell, Richard et al. went out after dark to CES 700 and the Contarana but saw no snakes. Earlier (daytime) Ardell got a Bothrops nasutus near CES 500 ($\approx 480+53$ mm, 98g, ♀ - [no] maybe gravid).

July 16 From 0830-1115 hr I walked SOR - Holdridge - Suampo - Camino Central to 1200m and back in via CCL and SOR. Before I left Cathy Pringle saw a small Erythrolamprus mimus (223+39mm, 5.2g) cross the sidewalk into palm litter in the lab clearing. When held it thrashed, tail coiled, expelled cloacal liquid, and elevated its flattened head and neck. At 0852 hr I caught an adult ♀ Spilotes pullatus ($1700+590$ mm, 780g) just before the origin of STO or SOR. The snake extended out of woods onto the trail, w/ its entire body in fight kinks! The resemblance to

Alees, H.
1989

July 13 (continued) swallowed head-first. at dinner Rodolfo Peralta gave me an Erythrolamprus miliaris (20.5 g, $364 + 14 + ?$ mm) he found this afternoon near the lab clearing. The snake crawls frantically, and when restrained elevates the curled tail, then pokes the hand w/ it. During repeated restraint for ~~for~~ photography it did not attempt to bite. The tail seems recently cut off. After dinner, Ardell, Silvia Barahona^(A.C.R.), and I walked to CES Zoo and saw only a large Agalychnis callidryas walking on a slender (≈ 5 mm) branch or vine, ≈ 3 m above the ground - its blue and yellow flash stripes and red eyes very evident in my light beam. David and Billie Hard walked to ≈ 700 m on the CCC and back through the Cartarava Swamp. They saw a ≈ 4 ft. Bothrops asper coiled beside the trail at CCC 440m - it remained still during a couple of minutes of photography, then crawled into the forest. They brought in a Tephritis septentrionalis from the Cartarava Swamp (25g, $530 + 195$ mm). Found the Lachesis muta in same place, head not up and alert, at ≈ 2130 hr. At ≈ 2200 hr an undergrad. from U. Florida (Marcie) showed me a "water snake" in the ^{Cartarava} swamp that was an eel - I think Synbranchus marmoratus because I could not see pectoral fins. It was resting in vegetation just beneath the surface, opercular movements visible - ≈ 15 mm in diameter, maybe ≈ 30 cm long.

Heene, H.
1989

July 16 (continued) a root was impressive, and I don't think the snake did it in response to my approach. In fact, it appeared unaware of me until I touched its neck w/ my book. When seized it bit repeatedly, holding on and chewing a few seconds before release; and vibrated the tail strongly for a considerable portion of its length. also inflated neck when held. at 0908 hr, SHO 700 m, a Leucosternis semiplumbeus flew across the trail from a low branch and landed \approx 10m up on a branch facing away from me - was it hunting by the trail for reptiles? at 0928 hr at \approx 544 600 m, where the trail parallels a stream, an adult Basiliscus plumifrons jumped in the water \approx 15 m ahead of me, then ran \approx 10 m and parallel to the bank before emerging. Dave Hardy got a Leptophis nebulosus at CES 500, on a pole (455+297 mm, 12g). Ardell found another Bothrops mosatus at the same place (256+29 mm, 17g). Richard Foster saw what was clearly an adult Homopeltis triangulum on the Zoop Trail, but it escaped in litter. I gave an evening talk on Tropical predators to a field course run by Cathy Pringle and Jim Aftel from the UCB Botanical Garden. afterward, Dave Hardy found an Eleutherodactylus fitzingerii (SV 47mm, 8.5g) on the sidewalk - fed it

Greene, H.
1989

July 16 (continued) To the black-and-orange Motheca. At 2045 hr Deborah Clark showed Ardell & a Sibon nebulosus ($490 + 166$ mm, 23g) crawling across the sidewalk. When handled the snake retracted into an exaggerated S-coil w/ quadrates spread, jerky false strikes, and cloacal discharge. At 2115 hr Ardell found an Dipsas cerehoa ($640 + 280$ mm, 18.5g) in leaf litter during heavy rain, at CES 550 m - only a cloacal discharge when handled. At \approx 2200 hr Richard Foster and Carol Farnelli took Ardell and I to an adult ♀ Bothrops asper ($1563 + 200$ mm, 1.75 kg) on a slope beside concrete steps at the SE side of the Cartagena Swamp. The snake was in a loose coil, w/ head and neck raised \approx 20-30 cm and an angle of $\approx 60^\circ$, immobile. Ardell and I had no trouble getting her in a garbage can using two hooks. Never struck - always tried to crawl away.

July 17 Alejandro Solozano arrived at noon, and we walked in the afternoon out 502-540-51A and back by way of CCC. No snakes. After dinner Alejandro and Ardell and I walked out to CES 5700, and caught an Dipsas cerehoa ($7681 + 315$ mm, 14.5g) at CES 65 m, 2045 hr, crawling in leaf litter - no defensive behavior.

July 18 The temporal continues - days of cool weather and lots of rain throughout the day and night. This morning we anesthetized the big ♀ Bothrops asper

Greene, H.
1989

(clipped 3rd ventral ant. to anal plate, on snake's left)

July 18
(continued) To measure and otherwise examine her. Ardell got her up in a tube w/out difficulty. Noted two old scars, one anterior on left side neck, the other on L side of posterior body - the latter w/ obvious broken ribs. In the afternoon Alejandro and walked to Camino Central 1300 m and spent some time off trail in what seemed like excellent Lachesis habitat. We went out CCC and back CCH, saw only a possible Montiviperas or Dendrophidion that escape under a stilt palm. At 1930 hrs Carol Farnetti led me to an adult ♀ Bothrops asper (1700 + 234 mm, 2.05 kg) coiled beside the trail at CES \approx 100 m. She was perpendicular to and facing the trail, w/ head out over coil and parallel to ground - very nicely aimed at the boardwalk. Had to hook her into a can by myself (Ardell and Alejandro elsewhere), and once she got into the woods a few meters, off sword I led 10 students of a UCB Botanical Garden course on a nightwalk to SOC \approx 500, then to Cantarana - saw only 2 sleeping Norops limifrons on leaves, and frogs.

July 19 After lunch we anesthetized and examined the second ♀ B. asper (clipped 4th ventral, on snake's left) - she started up the tape and then shot up almost to the top before I grabbed her! We noted no external injuries, but her left fang was broken several mm above the tip.

August 13

Portal, Cochise Co., Arizona

arrived here \approx 1430 hr after a roundabout trip across the Sierra Nevada, Nevada, and southern Utah - I had forgotten how spectacular the red cliffs around Bryce Canyon look in afternoon sun. Billie Hardy has a friend staying w/ her at their place, so I will stay w/ Barney Torberlin at Vince Roth's house. Drove up Cave Creek Canyon \approx 1730 hr and stopped to chat w/ Kim Murphy, the local game warden. Told me about shooting a lion from horseback, w/ a .30-30, in the Peloncillos years ago. After dinner I road hunted from \approx 1900 - 2200 hr: out to the Sistrurus catenatus site on Hwy 80, made 2 passes there, then back and up Cave Creek Canyon to SWRS and back. Before dark I saw a large Crotalus atrox start onto the road just east of Portal, then rapidly crawl back off. A few minutes later, a very reddish subadult was crawling in the center, and I moved it off. Caught an adult C. scutulatus (no food in sc, gave snake to Barney) 5.1 mi E. Portal at 1930 hr. Saw fresh DOR Thamnophis marcianus 4.5 mi SW (1985 hr) and 6.4 mi SW State Line Rd. on Hwy 80, and shortly thereafter a freshly lit Crotalus scutulatus that I saved. On the way back a live Uromastyx gularis and then a Crotalus molossus crawling off.

1989

- August 13 (Continued) Cave Creek Rd. just as it started raining. All evening there were heavy electrical storms on the surrounding mountain ranges. Rained into the evening.
- August 14 Arranged things for surgery tomorrow, talked to David Hardy in Costa Rica, and checked two drift fences on the Paradise Rd. w/ Barney Tomberlin. From \approx 1900-2230 I road hunted out Portal Rd & Hwy 80, made two passes over the Sistrurus site, and went up the canyon to SWRS. Saw 6 snakes: 2 neonate Crotalus scutulatus, an adult Pituophis melanoleucus (2028 hr) at the Sistrurus site bridge (21.4 mi SW State Line) and a neonate Pituophis on the Portal Rd. (2211 hr), and two adult C. scutulatus (one on State Line Rd. and one preserved).
- August 15 At 0940 hr Bryan Jennings (UCSB undergraduate) and I missed an adult Masticophis bilineatus on Cave Creek Rd a few 100 m NE of the Hardys' house - it was immobile on the road when first spotted, but rapidly glided off and we couldn't find it in the mesquite. At 1120 hr I spotted a subadult Elaphe kingii rapidly undulating off the edge of Barney Tomberlin's driveway in Portal. Operated on a pair of Crotalus molossus found by Tony Snell in the same sycamore grove where we began tracking the male blacktail last year - surgeries seemed to go fine. Barney and Tony and I ate an early dinner and were at the Sistrurus bridge site, 21.4 mi SW

1989

August 15 (continued) of State Line Rd on Hwy 80, by 1900 hr and we walked onward W of the Hwy for \approx 1 hour. The site is very reminiscent of the Kansas Flint Hills locality where I first saw Sistrurus in 1963 - gently rolling grassy hills, cut by a shallow winding dry gully w/ small rock outcrops and many volcanic rocks over the landscape. Many rocks are well-inbedded, but some are flat and liftable. In the past, they've seen C. atrox, C. scutulatus, Sonora, Eumeces obsoletus, Holbrookia maculata, Gemidophorus uniparens here, and there is a report of Lampropeltis triangulum. There are Neotoma nests in the rock outcrop, and as Tony looked into the first one he saw an active Elgaria kingii that escaped into the tangle of sticks! Only other prep was an adult Crotaphytus collaris I found sleeping under a small flat rock. We got 7 snakes road hunting, 2 Crotalus scutulatus, 2 C. atrox, 1 Tantilla nigricans, 1 Lampropeltis getula, and 1 Microlophus occipitalis - between \approx 2000-2230 hr - We had driven out to Bernardino, made two passes between there and Rucker Canyon Rd., gone back up to SWRS, and then out the Portal Rd \approx 3 mi before returning to Basney's home.

August 16 at 1130 hr I caught an adult Masticophis bilineatus on Cave Creek Rd, at a place where there is open grassy "parkland" on one side and oak woodland

Greene, H.
1989

August 16 (continued) on the other. Snake was immobile in a sun patch, and only dashed off the road as I approached on foot. Squirmed and bit when seized. At \approx 1230 hr we released the Crotalus molossus at their original capture site, a Neotoma nest built into the side of a pile of drifted branches in the canyon bottom. Barney Tomberlin and I drove to Bernardino and back between \approx 1600-1840 hr. at 1610 hr we found an adult Crotalus scutulatus crossing State Line Rd. There was a very DOR Heterodon nasicus adult on Hwy 80 at Bernardino, hit today since it wasn't there last night. From \approx 1630-1800 hr Barney and I walked up to the old cinder mine, 22.2 mi SW State Line Rd on Hwy 80, W of the Hwy. The ground is muddy and there is standing water in places; shy overcast, humid, almost cool. We caught 3 Sceloporus undulatus, 1 Cnemidophorus uniparens, and a pair of Crotaphytus collaris under rocks and old boards. Barney spotted a small Phrynosoma douglasii (or modestum?) crawling among small rocks in open ground; piece of shedding skin around head. Several Sceloporus escaped because they dove into the bases of "bunch grass" (?) when startled under rocks. After preserving the lizards and a fast dinner, I road hunted to Bernardino and back, up to SWRS, out to 2 mi E. of Portal, and

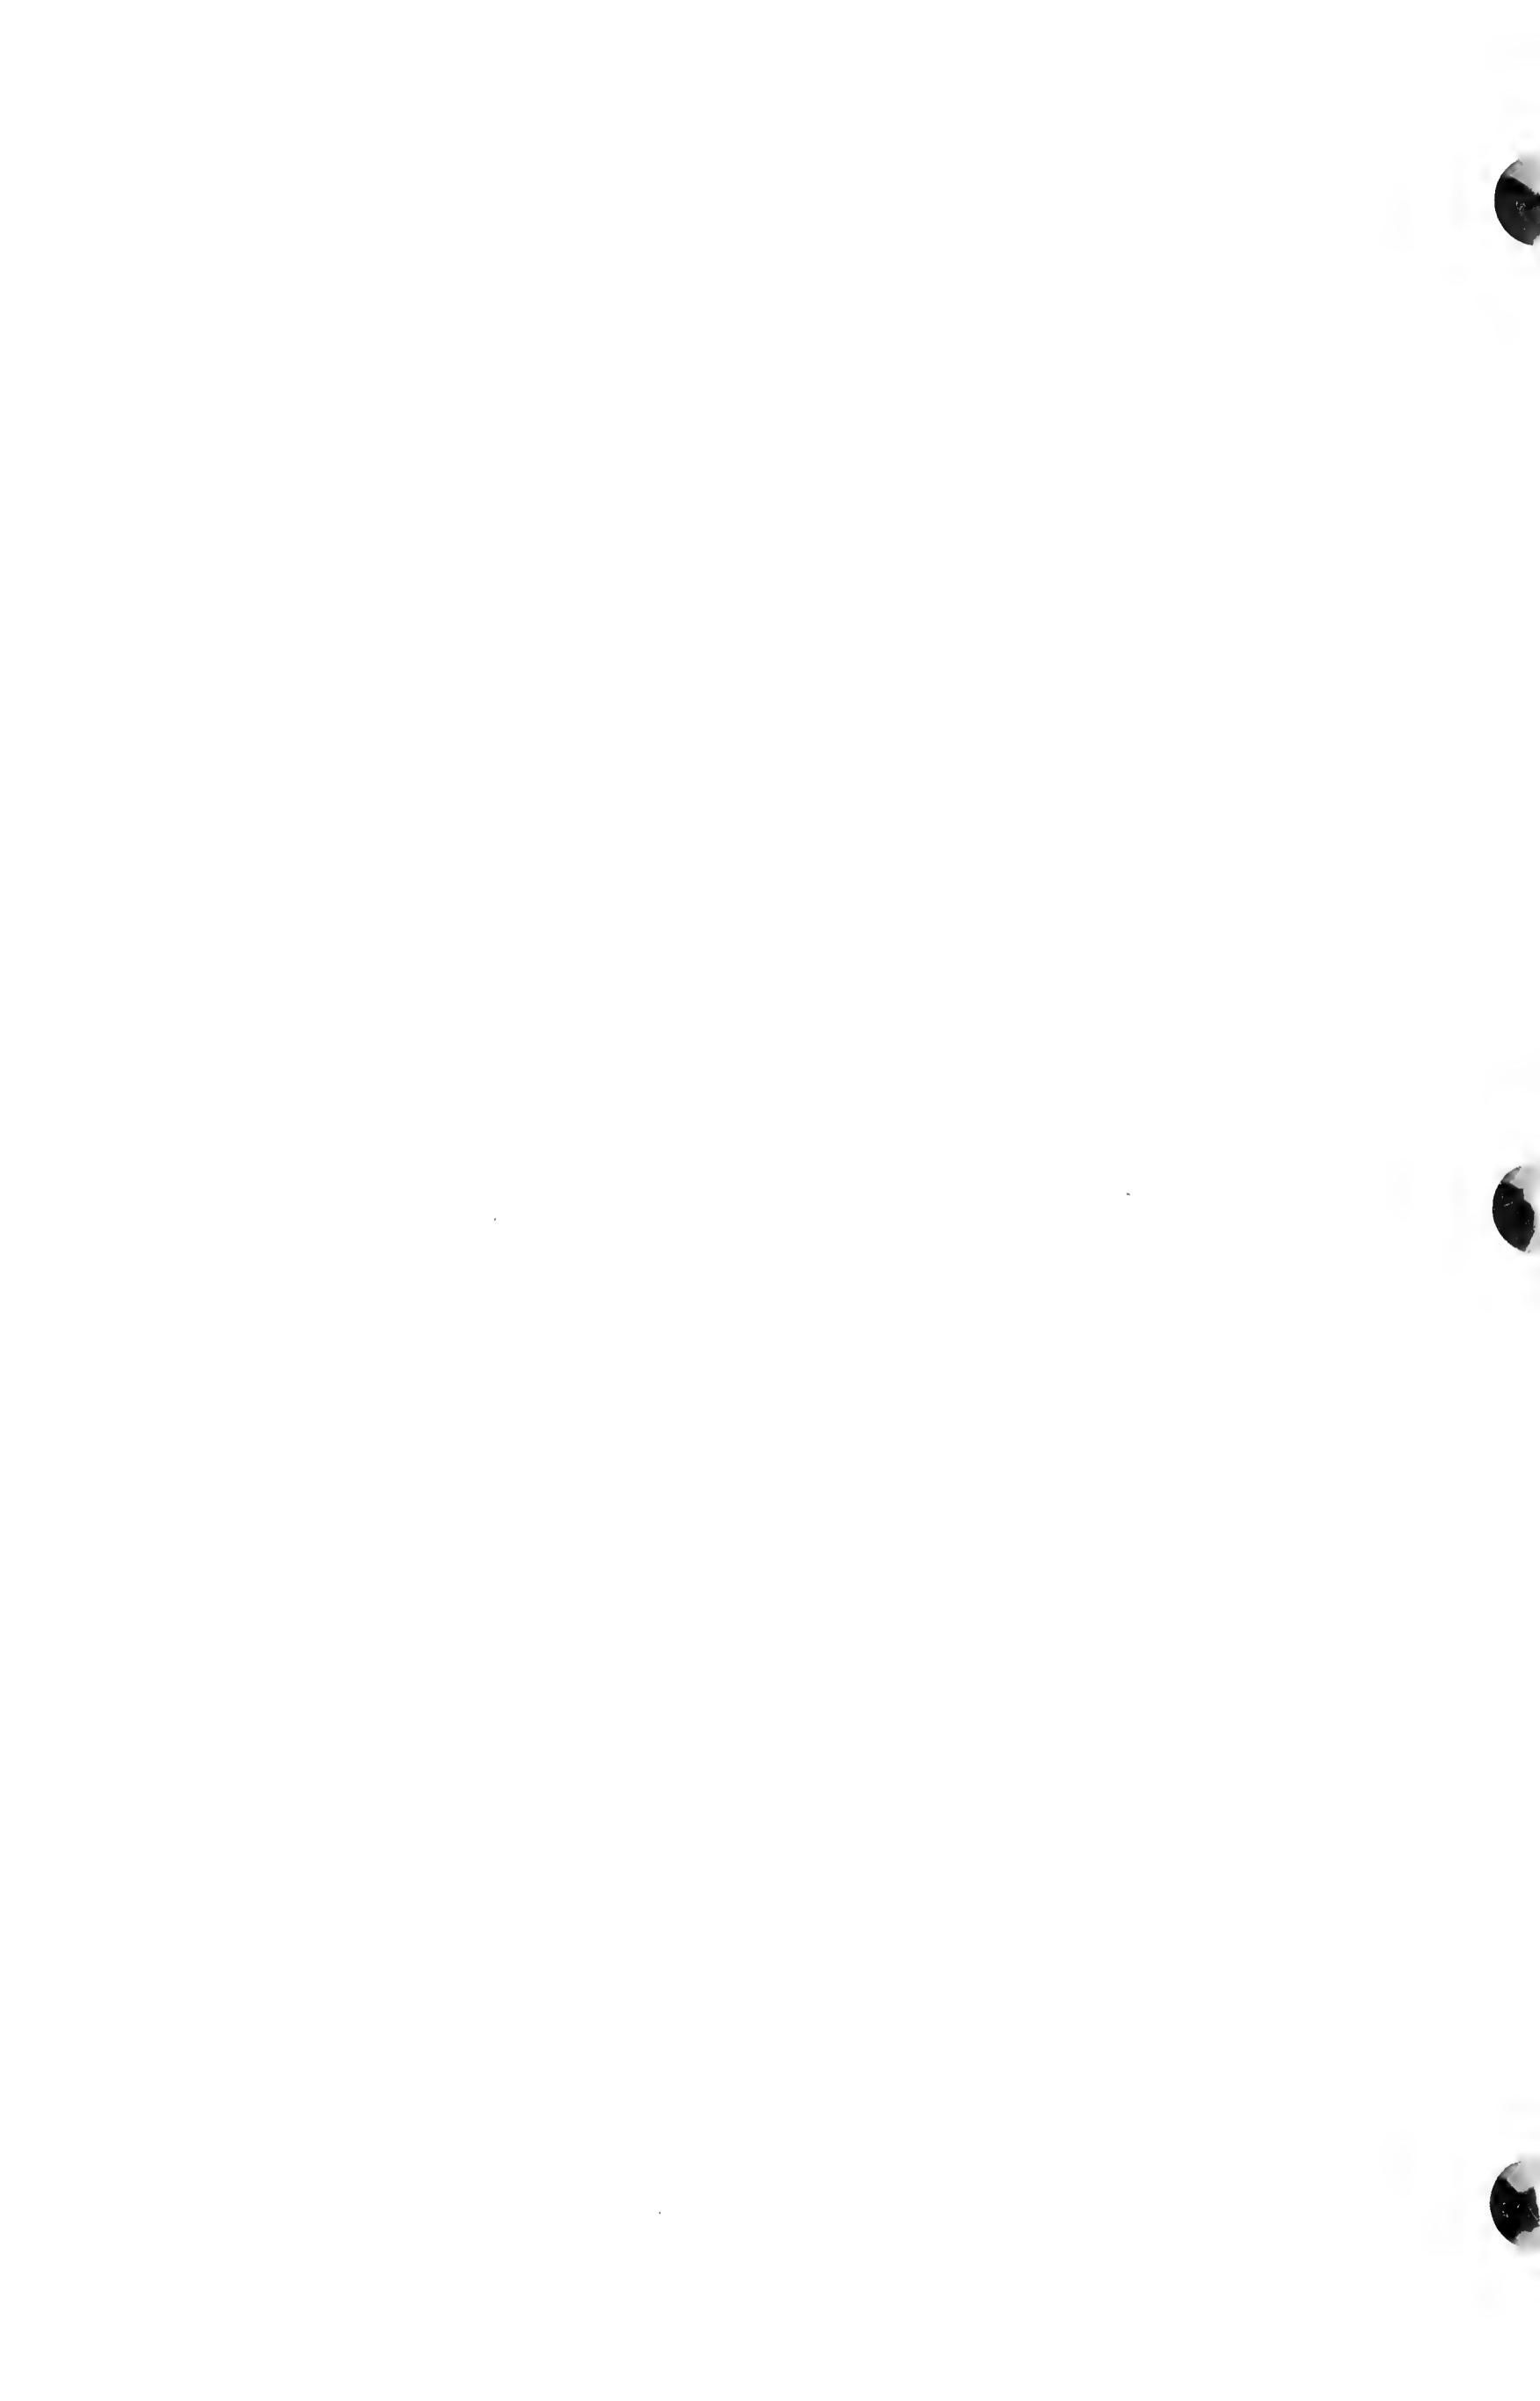

Greene, H.

1989

August 16 (continued) back to Barney's house, from \approx 2000-2240 hr. Until \approx 2200 hr the sky was exceptionally dark, due to a full lunar eclipse and heavy cloud cover. This plus large electrical storms all around the valleys made the night spectacular. Saw a neonate Crotalus (2201 hr) and subadult Pituophis melanoleucus (2207 hr) on the Portal Rd, nothing at the Sistrurus site on two passes, and only a Thamnophis marcianus on Hwy 80. Got an adult hognosepitis getulae at 1.6 mi NW Hwy 80 on State Line Rd. at 2135 hr - the snake was crawling as truck approached, and tried to crawl away rapidly as I got close. Only response to handling was to sputter - but it later crawled through the snake bag knot and escaped in Barney's house. Got ~~three~~⁴ snakes on the Portal Rd: a Tantilla signiceps that squirmed w/ body rigid and chewed my finger repeatedly; two adult, very nasty Crotalus scutulatus (4.5 mi E. of Portal at 2153 hr, very yellow; 2.1 mi E of Portal, 2200 hr); and a neonate Trimorphodon biscutatus that only squirmed when handled.

August 17 Spent an hour or so w/ Diane Wagner (former UCB undergrad, now at Princeton U.) at her butterfly study site E. of Portal. At \approx 1115 hr we used ~~silently~~ to locate the two Crotalus molossus, \approx 50-60 m uphill from where they were released yesterday. The snakes were lying together under a flat sloping boulder,

Greene, H.
1989

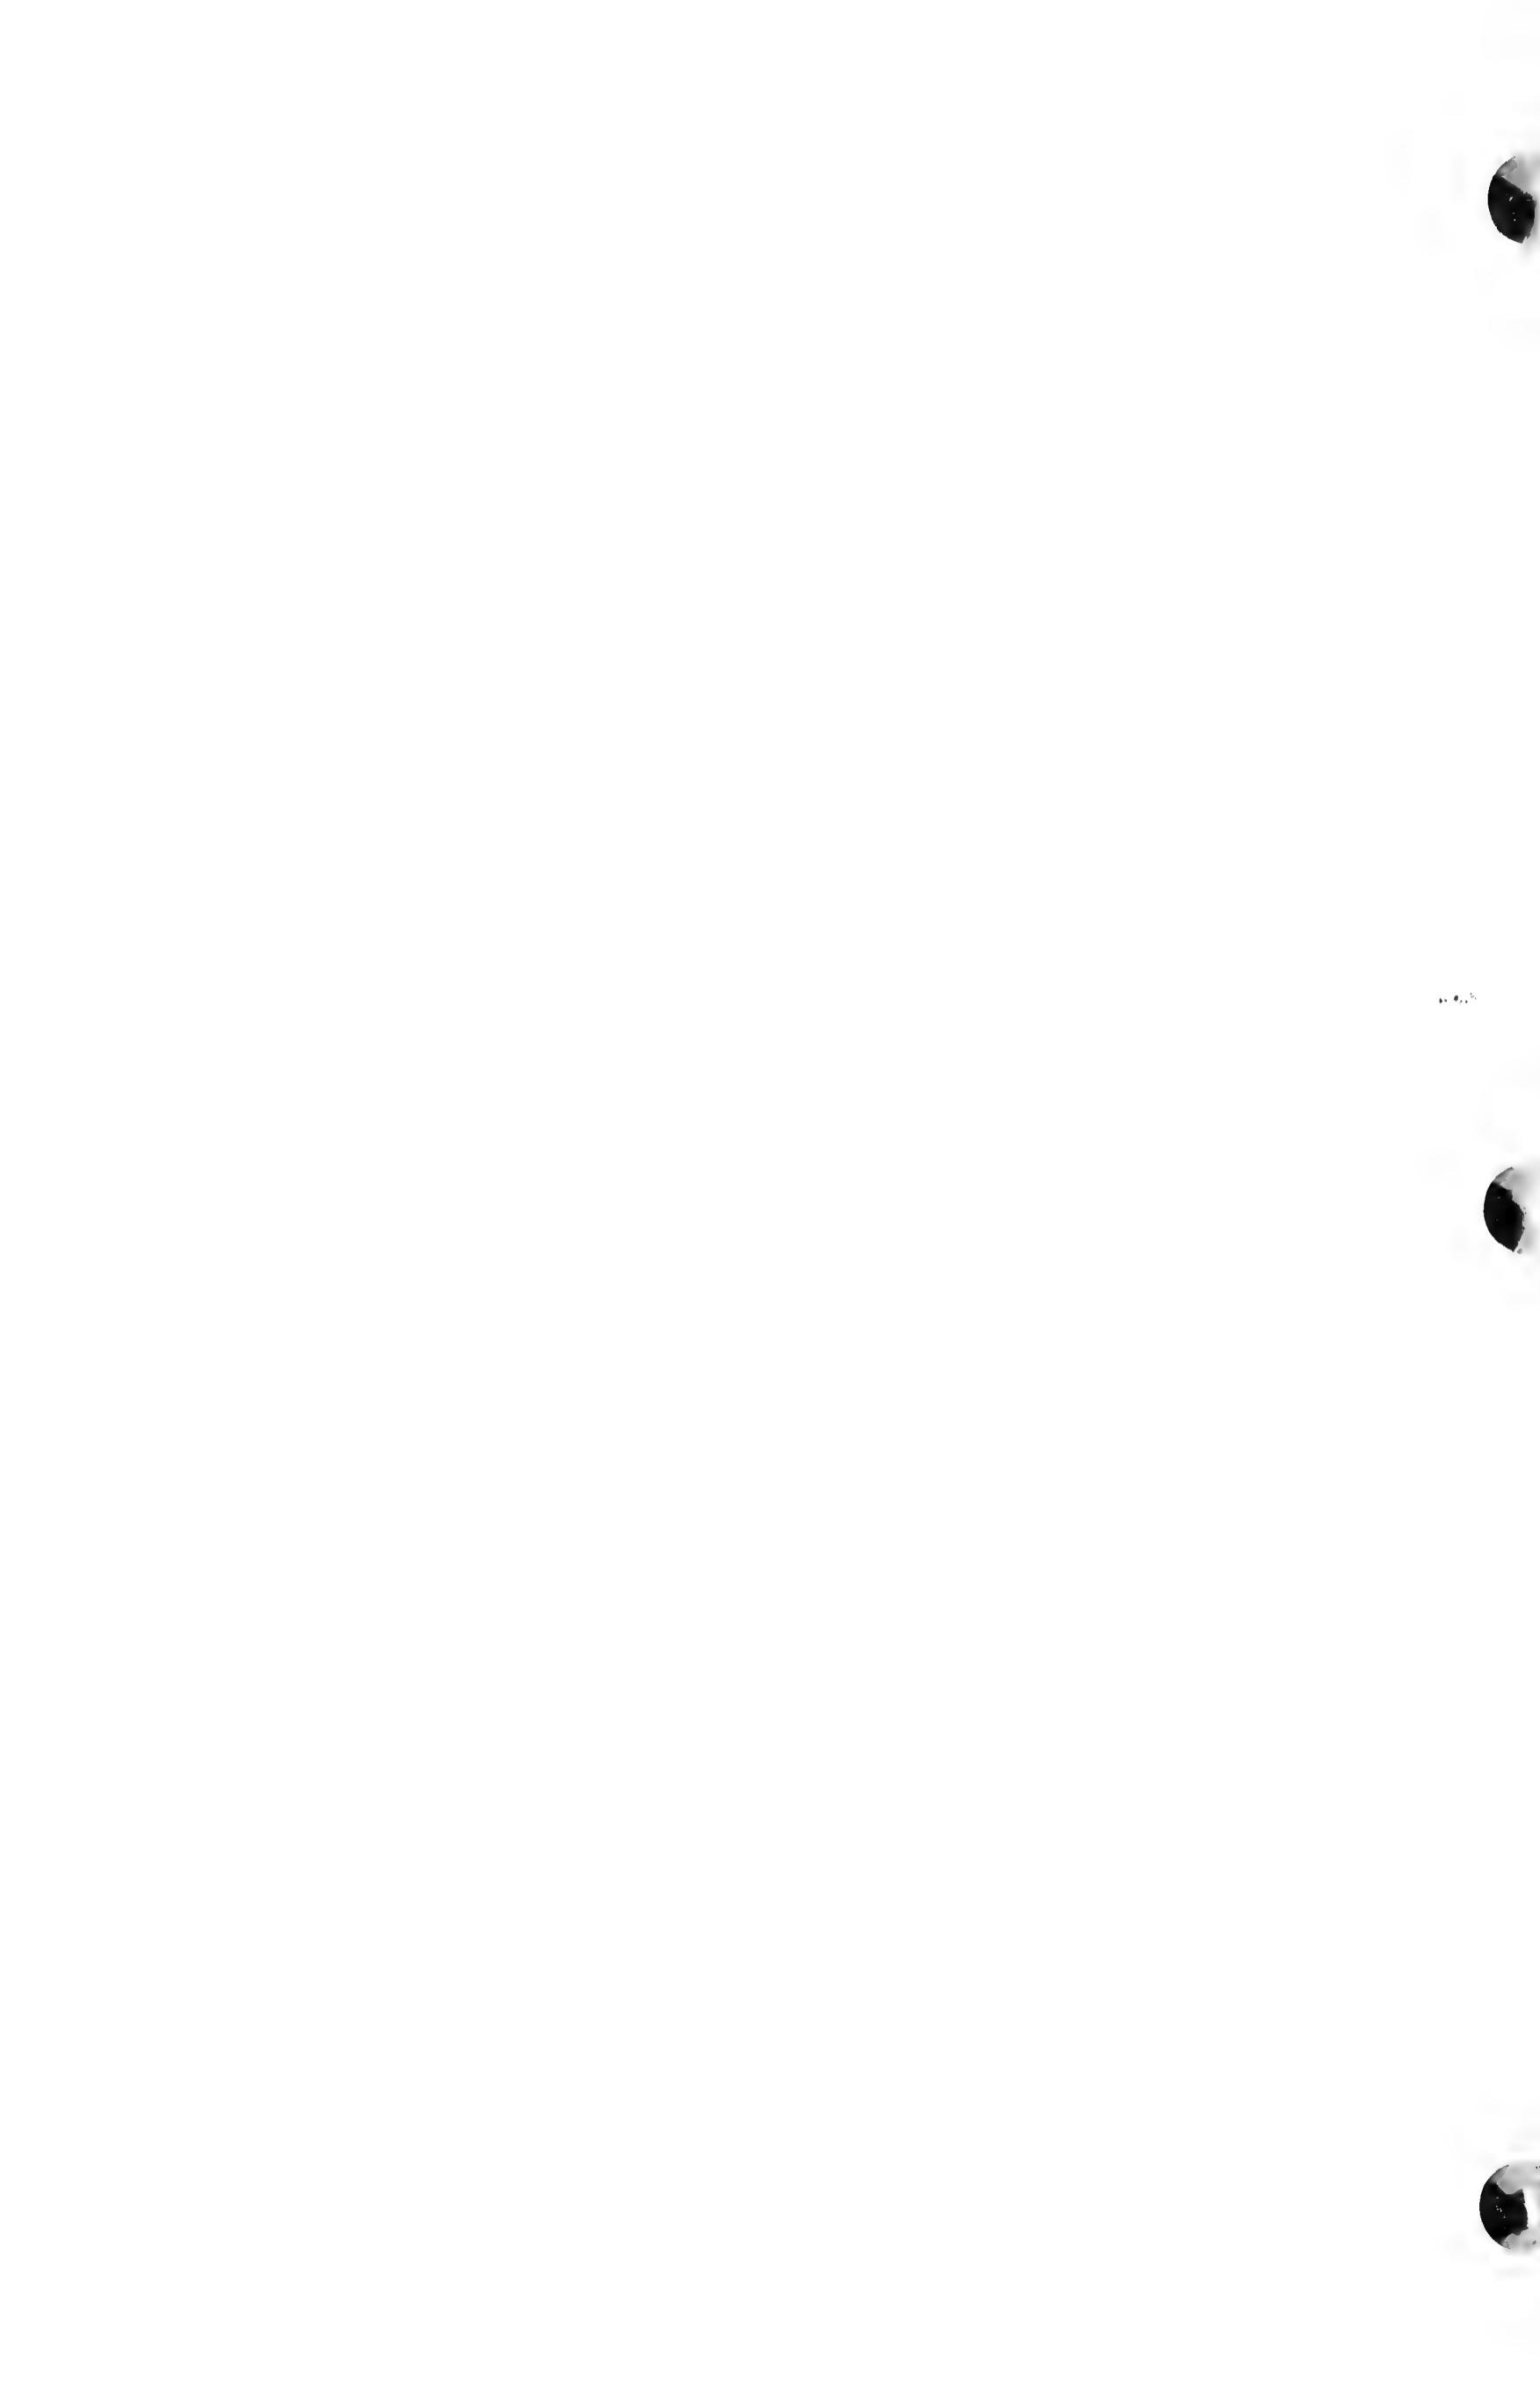

August 17 (continued) under thick mesquite near Paradise Rd. The ♀ was in a tight flat coil in blotched sun, w/ rattle hidden. The ♂ was part in sun (head and tail), partly hidden under the boulder. An impressive sight! After a couple of minutes the ♂ clicked his rattles (we were \approx 2-3 m away) and pulled back under the rock. At \approx 1400 hr a Spilogale variegatus moved away from the boulder as I approached - unclear if it was startled by my approach or behaving nervously because of the snakes. Now the two snakes are together under edge of the boulder, heads adjacent and pointing out in sun. I took some photos, and eventually the ♂ rattled briefly and withdrew under the rock. When I checked again at 1645 hr it was dark cloudy and cool, and I could only see the edge of the ♂'s coil. I gave a talk at the SWRS after dinner, and road hunted from there to 2 mi E of Portal and back to Barney's at 2230 hr - saw nothing. There was a heavy thunder storm during my talk, and afterward Wade Sherbrooke (SWRS Director) took out on a narrow foot bridge over the Middle Fork of Cave Creek. The stream was in flood and I could hear a roar of boulders being rolled in the stream - as if they were in a rotating drum! When I reached Barney's house, the stream in front of his house was high enough that I elected

Greene, H.
1989

August 17 To park and walk across on the foot bridge
(continued) rather than drive across.

August 18 Spent the morning picking road kills Barney
had frozen for me. At ≈ 1400 hr located both
Crotalus molossus signals under the same boulder
and could see an edge of the ♂'s coil. Good
rain started ≈ 1430 hr.

Greene, H.

October 19

~~Portal, Cochise Co., Arizona~~

arrived here \approx 2300 hr last night, having flown in from San Francisco via Salt Lake City and picked up David Hardy's jeep at the Tucson Airport. Surprised I was able to travel, because at 1704 hr on the 17th we had a \approx 7.0 earthquake and the airport was closed for a few hours. This AM Basney Ton Berlin and I stopped on the Paradise Rd \approx 1.5 mi W of Portal in shrub, and I found an adult Crotaphytus uniparens inactive and dirt crusted in a burrow under a small rock. Then we checked for the two telemetered Crotalus molossus, but they were not visible where he most recently saw them. Then we drove to the Krenz Ranch on Rucker Canyon Rd and obtained permission to look for herps from Mr. Krenz' sister-and-law, a Mrs. White. We drove \approx 2-3 km down a dirt track that extends out onto the range $\frac{1}{2}$ S. from Rucker Canyon Rd & \approx 2.5 mi W. of Hwy 80. Then back to the backside of two connected hills w/ rock outcrops that we explored earlier this year. I saw 1 hatchling Sceloporus undulatus, active on a rock outcrop, and Basney saw a Chrosaurus ornatus. A large Canis latrans loped ahead of us up the hill and over it, pausing every few dozen meters to stand in profile, ears up and facing us for a few seconds. At 1230 hr as I clambered over rocks in grass beside a >1 m diameter boulder, I heard a

Greene, H.

1989

October 19

(continued)

rattle and looked back to see a subadult Crotalus atrox where I just stopped, drawing under the boulder. Hooked it out and eventually bagged it w/ Barney's grab stick. Snake was very riled: body flattened, its struck repeatedly and wildly, and at least twice bit the snake bag. I was impressed that the mouth was widely gaped during the strike. Next we drove to Bernardino to watch for Sistrurus and picked up a DOR Heterodon nasicus that I thought from the car was a Sistrurus because of its dark pattern. Found a still thrashing DOR Pituophis melanoleucus on the highway back to State Line Rd. after lunch I returned to the Crotalus molossus site on Paradise Rd., and found our telemarked pair both basking by the sheltering rocks at which they've recently been sighted — some several dozen meters apart.
